Is it just replacing the tubes we should worry about? What about the complicated auto-tune mechanism on the 2000a?

You folks that have bought replacement tubes from Russia or whereever, what do you do when the tubes arrive? Do you just stick them in the closet and leave them there for perhaps years until the originals go soft? Or is there some easy way to at least test them? As it's so complicated to replace the tubes in the amp, I assume no one is putting the new tubes in now and then saving the originals for future replacement use.

That's the question I asked a month or two ago and the thread morphed into "you can't get any." Whether or not it is true that you can't get any, I plan on dropping a NOS replacement into my ACOM-1000 "as is" soon to find out. Probably will blow the tube, some of the control circuitry and any warranty left if I do this . . . :-)

I think the two tubes are supposed to be balanced (roughly the same charactoristics). I plan to leave my spares until the originals die in 6,000 hours and then follow the instructions. (Turn on in standby for many hours, etc.) By then we may have a new source for tubes.

Where did your 6,000 hour number come from? Is that "transmitting hours" or
does it include "standby hours"? If it's only transmitting hours then my
tubes are likely to outlast me :-)

That is a number I have seen for expected tube life. Likely transmit hours.

I normally leave my amp on 24/7, you never know when something you need will come on.

I left my 30S1 on for many years 24/7 and routinely got several years service from each 4CX1000A. Same result with my 3CX800A7 amp. I expect the ACOM finals to perform the same. I think it is harder on the filaments to run them through hundreds of on/off cycles than to leave them hot.

From: kamarty456
Topic: 2308 Message: 2308

I was wondering if there are any conflicts with the Acom 2000A and using a MFJ-998 1500w auto antenna tuner?

I need an in-line tuner for only 40 meters to tweak it a bit to keep the 2000A happy...no need to go into a rant so let's stay on the specific questions please.

I am also concerned with the "arc-fault" alarm when you have "slow switching" ... will the 2000A tolerate the MFJ-998?

Thanks for your comments.

Marty,

I use an MFJ 982, an older tuner, with my Acom 2000 to cover the entire 80 meter band and some WARC bands w/o problem. Never arc faults.

Thanks Paul,

Very nice article, thanks for the detailed info.

Still not a very pleasant choice for those who choose to invest in the replacement tubes: either 1) test them by tearing apart your amp and risk damaging the tubes/amp, or 2) leave them on the shelf until you need them and risk that they will work when needed.

It would be prudent to let the tuner do it's thing at 20-40W, with the Acom in bypass mode, as you QSY on 40M. Then when the tuner's happy you flip on the amp, and the tuner might make some other tweaks. But tuning at 1000+W with mismatch is inviting failures in the system. Get a good match at low power, then bring in the QRO.

I don't understand why this is such a big problem with the NOS tubes. Let's ask around the country for a company that will be willing to do the job of testing and bringing up the tubes to install status. After spending nearing $7,000,I really don't feel I have to go thru the procedure of playing close to 3000 volts and still not sure what I'm 100 percent doing is effective. This is a long way from plugging in thoses 6146Bs into the Heathkit DX100.

On another subject, I have a business trip coming up to St. Peterburg in July where the SED 4CX800A were produced. If anyone has infomation as to a contact person or anything else that would help, I would be glad to see what can be done to establish a flow of these tubes back to the states. I await your comments on the above.

There our two good auto tuners out there too handle the power of the Acom ,patstar AT will handle the power 1500 on all bands and Ten-TEC auto tuner 253 made to work with the titan amps used only $ 755. used if you can find one very good tuner.

MFJ will most likely melt if you put it on 160, these tuners our real a joke and to risk $6000 amp on a 200 dollar tuner is foolish. But that my opinion !

I think we make way too much fuss out of the fact that we
use NOS tubes as replacements. The UR4LL and ND2X description can be combined
together and this provides the solution to get the tubes started.

I am starting a NOS tube as I write this e-mail, begun with bringing up the
filament voltage up in stages, now entering the 12.5 volt stage (five 20% steps
in total, one hour each) and let it run for 24 hours. Next step is to install
the tube in the ACOM amplifier and let the amp switched on but IDLE for 24 hours
followed by some QSO's on 50% of output power for 30 minutes or so.

That should do the 'trick' nicely.

I e-mailed a year ago with Stanimir (Acom Bulgaria) and proposed this way. If
one needs Stans reply e-mail see below for my e-mail address.

BTW: If any badly one needs a spare tube, I have some spares for the ones who
really need one. Not cheap, and dull looking Svetlana tubes, but at least NOS. No guarantee
possible since these will have to be post parcel shipped but I check
the PINs on shorts and if needed, I heat up the filament on request. (No
matched pairs in stock). Contact me via personal e-mail for spares. Look at QRZ
for e-mail address if needed :-)

Hi Kees,
How do you heat up the filament without a socket and air flowing through it?
I would think the tubes would get very hot without a socket, but I don't
know.

I don't know a way to provide only filament voltage on the 2000A without the
software interlock shutting down the amp if I unplug the bias and high
voltage supplies.

I had bought a pair of NOS tubes. One showed a grid-cathode short after
about a minute of filament voltage applied. This was the same failure mode
of a tube after 6100 hours on it.

Subject: RE: [acom-list] Conditioning of the GU74B tubes for the ACOM 2000A.

I think we make way too much fuss out of the fact that we
use NOS tubes as replacements. The UR4LL and ND2X description can be
combined
together and this provides the solution to get the tubes started.

I am starting a NOS tube as I write this e-mail, begun with bringing up the
filament voltage up in stages, now entering the 12.5 volt stage (five 20%
steps
in total, one hour each) and let it run for 24 hours. Next step is to
install
the tube in the ACOM amplifier and let the amp switched on but IDLE for 24
hours
followed by some QSO's on 50% of output power for 30 minutes or so.

That should do the 'trick' nicely.

I e-mailed a year ago with Stanimir (Acom Bulgaria) and proposed this way.
If
one needs Stans reply e-mail see below for my e-mail address.

BTW: If any badly one needs a spare tube, I have some spares for the ones
who
really need one. Not cheap, and dull looking Svetlana tubes, but at least

NOS. No guarantee possible since these will have to be post parcel shipped
but I check
the PINs on shorts and if needed, I heat up the filament on request. (No
matched pairs in stock). Contact me via personal e-mail for spares. Look at
QRZ
for e-mail address if needed :-)

Hi Kees,

How do you heat up the filament without a socket and air flowing through it?

I would think the tubes would get very hot without a socket, but I don't

know.

I don't know a way to provide only filament voltage on the 2000A without the

software interlock shutting down the amp if I unplug the bias and high

voltage supplies.

I had bought a pair of NOS tubes. One showed a grid-cathode short after

about a minute of filament voltage applied. This was the same failure mode

of a tube after 6100 hours on it.

2322. Re: Acom 2000A and "other brand" auto tuner?

Yahoo group: acom-list (1999 — 2009)
Date: 2008-01-31 22:11:06 UTC
From: ki4ge
Topic: 2308 Message: 2322

Hi Marty,

I have been using a MFJ-998 with a Icom 756 Pro III and the Acom 2000a for about 6 months. I work exclusively on SSB. The tuner works great. I am using it with a HighGain HyTower vertical with 110 radials that are 110 feet long. The antenna has a radiation impedance of about 20 to 30 ohms on the various bands(probably due to the large diameter of the vertical and the large number of very long radials).

I operate the station by remote control using TX-Manager and TRX-Acom over the internet. The tuner works fine in this type of operation as long as it is autotune mode. I use the tune function in TRX-Manager to activate the tuner over the internet which applies about 5 to 10 watts during the tuning cycle.

2323. Re: 4CX800A tubes are available

Yahoo group: acom-list (1999 — 2009)
Date: 2008-02-01 02:32:40 UTC
From: Chris
Topic: 2239 Message: 2323

Yes, the tubes really are available....

I received the following reply from the vendor (tube-shop.com):
"Yes! I have stock"

They do sell to the U.S. and they do have inventory.

Outside of tubes, it is a general trend in the electronics industry
that components have increasingly limited production lifetimes. We
hams have been generally spoiled by the fact we can service our
equipment for many, many years after we purchase it. The lack of an
inexpensive out of production microprocessor, memory, I/O or other
chip can cause a radio or amplifier to become useless. So, do we buy
spares of everything? I don't know. Tubes do have a limited lifetime
compared to solid state devices so depending on how much key-down time
one does, it does seem prudent to be aware of their availability.

Dear friends:

I have been reading the mail regarding the GU7A4B tubes for the ACOM 2000.
Due the fact I have 3 of those linears, I started to be concerned about the possibility to have difficult for spare tubes.
I do have very good friend relationship with the ACOM´s people. They are very diligent in answering questions and technical assistance.
I got this answer from my friend Vasco the Chairman and CEO of ACOM, and he authorized me to spread the information to the ACOM´s owners.
I think we can be more relax now.
Best regards
Oms PY5EG

Dear Oms,

The rumors that Svetlana has discontinued the GU74B tube are not true. I visited Svetlana in St. Peterburg a couple of months ago and saw for myself its production was running OK and would even be increased.

The problem is that its price goes up!

ACOM has an adequate amount of GU74B tubes for warranty replacement only and not for "spare tubes" sales. However, there are GU74B vendors worldwide needing hams can buy tubes from.

Regards,
Vasco, LZ1JK

If the GU-74B really is in current production, this is turning out to be a scavenger hunt of epic proportion by Acom-list members to turn up a SINGLE recently manufactured tube for sale as a component anywhere in the world.

2327. Connecting the FT-950 to the Acom 1000 or 2000A

Yahoo group: acom-list (1999 — 2009)
Date: 2008-02-01 18:45:18 UTC
From: Hans Remeeus
Topic: 2327 Message: 2327

Hello to all!

Today I received the following information from Acom:

Control connection of FT-950 to ACOM1000 or ACOM2000A

1. The electrical specifications of the amplifier's KEY-IN input are
fully compatible with FT-950:
- Switching voltage (open circuit) - 15V max, plus to the ground;
- Closed-circuit current - 15mA max.

2. Connecting the YAESU FT-950 10 pin mini-DIN connector "LINEAR":

pin 2 (TX GND) - yellow - to ACOM "KEY-IN" RCA (CINCH) connector

pin 3 (GND) - green - to shields

pin 8 (TX INH) - brown - to ACOM "KEY-OUT" RCA (CINCH) connector

pin 10 (CHASSIS) - light blue - to shields

All rest pins remain unconnected.

3. Before connecting or disconnecting cables always switch off both the
transceiver and the amplifier.

4. In transceiver's menu 043 A1A BK-IN select "FULL" and in menu 049 A1A
QSK Time select a time delay of 15ms.

5. With the cable connected to FT-950 10 pin mini-DIN connector "LINEAR"
on one side only, and the "KEY IN" and "KEY OUT" RCA (CINCH) connectors
still not connected (free), the transceiver should not be capable to
transmit.

6. With the cable connected to FT-950 10 pin mini-DIN connector "LINEAR"
and the "KEY IN" and "KEY OUT" RCA (CINCH) connectors connected to ACOM
"KEY IN" and "KEY OUT" connectors, and the ACOM amplifier powered OFF,
the transceiver should be able to transmit and receive as normally.

7. With the cable connected as in (6) above and the amplifier powered ON
and in STBY mode, the transceiver should be able to transmit and the
amplifier should be keyed to operate during transmit and receive.

8. With the cable connected as in (6) above and the amplifier powered ON
and in OPER mode, the transceiver should be able to transmit and receive
as normally.

The ALC is preferably not used.

Please let the FT-950 and/or Acom Yahoogroups know your results.

2328. Auto tuner question solved

Yahoo group: acom-list (1999 — 2009)
Date: 2008-02-02 00:57:57 UTC
From: kamarty456
Topic: 2328 Message: 2328

I want to thank those of you who replied to my original question about what auto tuner to purchase. We can end the discussion.

Briefly:

I tried the MFJ-998 auto tuner. It is a nice box! I was surprised as to how noisy the relays are when they are banging away. The tuner tuned almost everything I asked it to and In a timely manner.

I was disappointed that the tuner does not provide a peak reading watt meter! It does offer a delay but only shows average power output. My manual tuner has a peak reading watt meter and I did not want to lose that feature. I returned the tuner.

I then tried the Palstar auto tuner. In a word "WOW!!" Amazing what an extra $700.00 will get you.
The tuner is well made and an excellent instruction manual. They also provide you with all necessary cables. They give you the interface cable between the computer and tuner should you want to add any updates! They also provide a spare meter lamp, some extra screws, and even a few Q-tips to keep the innards clean.

The tuner did tune everything I asked it to and quickly. The stepper motors are louder than what we hear in the Acom but in the big picture very quiet and smooth.

I will keep the Palstar. To be fair, I want to repeat the MFJ-998 is a good box too, but lacks the peak reading watt meter.

regards,
Marty KA7GKN

I'm sorry but what I've been reading about the GU-74B/4CX800A tubes doesn't make any since. The tube is being manufactured by Svetlana in St. Peterburg and there is no indication by Svetlana that they will discontinue there production. Why then are all the US and European distributors ignoring orders and information requests? Is a false tube shortage being created to increase the price? What would it take to contact Svetlana directly for a group buy? Would acom or perhaps one of the local radio clubs be willing to undertake such a venture? I do not have a business operation to run it through but would be more the willing to help.

What is the current price for this tube?

2331. E-bay VS gu74b/4cx800A

Yahoo group: acom-list (1999 — 2009)

I have been watching the tube dilemma very closely. I'm also in the market for a spare set of tubes for my Acom 2000A.

I have noticed recently a surge of tubes offered on E-bay.
I am a bit skeptical as one seller wants a check or money order without any guarantees!

Are there folks here that have purchased tubes via E-bay? If so, I'd appreciate your comments as to the experience. I wonder about how "truthful" the sellers are, as NOS [new old stock] or are they indeed pawning off rejects and junk.

regards,
Marty KA7GKN

Hi Marty,

I see eBay bids for an GU74B ending up to 267 dollars, amazing!!

My recommendation is always pay via PayPal, if goods are not as expected, ask you money back via PayPal. In the last year I had a few tubes DOA, and all three times my money was returned within one month from PayPal.

BTW: 'No guarantee' means NO WAY I buy from that seller!

It's pretty sad when we are reduced to buying tubes of unknown origin or condition from anonymous sellers. While it's great for ACOM and other amplifier manufacturers to tell us they visited the Svetlana factory, and that they (Svetlana) are ramping up production and that there are lots of tubes available, I have two questions:

(1) If Svetlana (or anyone else) is making these tubes, why can't anyone buy one?

(2) If Svetlana (or anyone else) is making these tubes, why won't ACOM sell us spares? "Warranty Replacement" is fine, but their warranty is a RTF (Return To Factory) for 2 years with the 1000 and for 4 years with the 2000. Why not sell us the part that is most likely to fail (the tube) and let us change it ourselves?

When the only option to get spare tubes for a top of the line amplifier is eBay, something is wrong. Why are ACOM (and Alpha, QRO, Emtron, etc) not selling spares? Why can't RF Parts, the most well known tube supplier in the world, get any?

From the Tube-Shop.com website:

"Sorry, Tube-Shop.Com are unable to sell Svetlana Tubes to the United States of America." It also appears from their product card that they sell the Svetlanta 3CX800A7 (triode) not the 4CX800A7 (tetrode). I didn't know that Svetlana had made a triode version of the tube.

> "When the only option to get spare tubes for a top of the line amplifier is eBay, something is wrong. Why are ACOM (and Alpha, QRO, Emtron, etc) not selling spares? Why can't RF Parts, the most well known tube supplier in the world, get any?"

If these companies are not selling spares to end-users, I would suspect that supply is critically limited at this time and the amp manufacturers need what tubes they do have on-hand for the manufacture of new product and in-warranty replacements for which they have an obligation. It doesn't exactly instill a feeling of confidence about owning an amp that uses these tubes.

Whether it's an amplifier or any other product, purchasers assume a high level of risk when a mission-critical component is manufactured by one single source of components with a short product life span. We're seeing evidence of this with transceivers manufactured as recently as five years ago. If a single source disappears for any number of reasons (e.g., obsolescence, arson, acts of God, terrorism...bankruptcy, etc.), the user is left to come up with a viable "Plan B?"

Here is the answer to your question #2

If a person, no matter how qualified, kills or injures themselves
in the process of re-tubing an ACOM or any other amplifier,
there will be a string of attorneys chasing the money,.....
it's called Liability......at least that is how
it works in the U.S....not sure about Canada or other countries.

TO OWNERS OF LINEARS USING THE 4CX800A CERAMIC TUBES

That's nice and all but no one is trying to establish a plan to purchase this tube anywhere. Let me roll this one out to everybody.....

I need to know how many linear owners would like to purchase these tubes as my company presently buys and sells electronics worldwide. I will attempt to purchase from Europe a minimum of 100 4CX800A to be sent to my office in the UK. If this is not going to work, I will be asking one of our overseas trading partners to do the purchasing for us in Europe. If there is some kind of game being played as to not allow the US to purchase, this plan will overide that. Also the pricing will be kept to a small percentage over cost if these tubes ever come alive in the future from companies here.

With the above in mind, I need to hear who would be interested in future purchases? Hopefully in two weeks from now I would like to obtain some idea what we're talking about in quanity.

Again, this is just an idea....

Before anyone responds to this offer, you may want to review archives of the Towertalk reflector. I've never done business with K2QBV, but his call rang a bell. It appears a bunch of people sent him money for towers and had some issues with getting what they paid for. I did a little searching and came up with this old thread. I believe there are others, too:

Hams have been changing tubes for 80-90 years. Since when did the liability issue come to the forefront? I know anyone can sue anyone in the US or Canada or anywhere else, but this is not a new technique, nor is it more or less dangerous with a 4CX800A than with any other kind of tube.

That is not the answer . . . for if it were we wouldn't be able to get 811As, 572Bs, 3-500Zs, 8877s, etc. RF Parts would not be in business. Whatever is going on is specific to the 4CX800A/GU74B tube.

I suspect this is part, if not all, of the reason Acom won't sell tubes unless you send the amp back to them for warranty repair. The 2000A requires the bias to be set when you change tubes. It's not a difficult procedure, but it does require the amp to be adjusted with the cover off and the interlocks defeated, exposing the customer to lethal high voltage.

The procedure is not in the manual. When my amp was new, and under warranty, I got a screen current fault that indicated a bad tube (probably damaged in shipment -- those screens are delicate.) Acom USA insisted on changing the tubes for me at their repair depot. Luckily for me, a few days later I was to attend a conference in Boston, which is only an hour away from Acom USA and two hours from my QTH. They met me at the hotel, picked up the amp, took it to the factory for repair, and returned it at the end of the day, repaired at no charge. Can't beat that for service! But most customers aren't located as close to Acom USA as I am.

It's interesting that instructions for adjusting the tube bias have been sent by Acom in Bulgaria to owners who asked for them. I would imagine this kills their liability protection, but perhaps the Bulgarians believe that would be Acom USA's problem.

I often wonder about the validity of keeping spares on hand. First, the life of these tubes is generally quite long in most amateur service. I'm an active contester and push my amps hard about 7-8 weekends a year. I guess that comes out to about 400 hours per year, much of which is spent transmitting at full power. In-between, they're not powered up unless I'm testing or chasing the last of the DX I need (done with that for the most part.) More than seven years after purchase, I'm still running the OEM tubes in the 2000A (well, one was replaced shortly after I got the amp.)

I'm also running the OEM tubes in my Alpha 87A, which is 12.5 years old. That amp is on my preferred run radio, so it gets pushed a lot harder than the Acom, which is used mostly for S&P. About 3-4 years ago, I started getting intermittent cathode current faults on the 87A, and identified the tube causing the problem. I bought a replacement Eimac 3CX800 from Alpha (expensive!) It was interesting that they didn't seem concerned that the tube might not match the good OEM tube. Not long after installing the new tube, I started getting serious power supply faults on the 87A. They were very intermittent and not the kind of faults you generally see with bad tubes -- or so I thought. The faults got worse and worse (should have been a clue), to the point where fuses would sometimes blow. Eventually, I ripped the amp apart and tested the HV and LV boards,

in some cases desoldering components to do so. I found no problems. By this time, the amp wouldn't start at all, or it would blow fuses immediately. I was sure the amp would have go back to Colorado.

Finally, it dawned on me that all the symptoms could be caused by tube arcs. The 87A fault checking isn't particularly good: it's not interrupt-driven, and the order of sensor checking can produce misleading faults. I removed both tubes and the amp started (it doesn't fault during warmup when the tubes are removed.) After that, it was a simple matter to determine which tube was bad, and it turned out to be the new one. Evidently, it was gassy when I received it, and the leak got progressively worse. I would have expected this to come to light during Alpha's checkout and gettering run, but perhaps they didn't actually do it (the company was under different ownership back then.) They took the tube back, verified the problem, and put in a warranty claim with Eimac. After a long wait, Eimac replaced the tube at no charge. The new one worked fine.

Not wanting to be without an amp while waiting for the warranty replacement, I retrieved the old OEM tube, which I had loaned to a friend for testing his Ten-Tec Titan amp (he hadn't gotten around to it yet.) I figured the occasional cathode current fault would be tolerable. The old tube worked perfectly in the amp, no longer causing filament current faults. My theory is that I didn't seat the tube properly in the socket when I was swapping tubes around to chase down another fault that turned out to be unrelated to the tubes. That OEM tube has been back in the amp and working fine ever since.

One other point. Is it a good idea to store spare tubes on the shelf for long periods of time? I've had bad experiences with 3-500Zs in this regard. My understanding is that the rubber seals dry out over time, and the tubes leak. The result, of course, is arcs. Are the 4CX800 and 3CX800 ceramic tubes subject to this? If so, then it makes more sense to get replacements with recent manufacture dates when and if you need them. Could be problematic for the Acom 2000A unless we can find a source for new (not NOS) Svetlana tubes.

Sorry for the long post. Sunday morning idle chat.

Dick,

Yeah really great service if you can "drive it in".

The ACOM2000 I used to own had two faults (both bad tubes) when under warranty. It required shipping amp back (then $90 a pop, now probably much more. Insurance is the killer in the rate. Now they have addition charges for "heavy" and oversize as well). That's how the rest of the world lives.

ACOM did return it in a reasonable amount of time-- about a month. Shipping ate up almost 2 weeks of this.

I'm not complaining.

Too bad the 2000 didn't include 6M. I'd still be using it rather than a 1000.

Appreciate your comments Dick. I just wanted to briefly respond to two issues you mentioned:

1. "I often wonder about the validity of keeping spares on hand." I had a tube fail without any prior symptoms, one week before CQ WW. Luckily, I was able to "borrow" a spare from a fellow club member, who WAS prepared. The lesson is that I NEED to have spare finals on hand, especially when the replacement was eventually purchased overseas with a transit time of several weeks.

2. "Is it a good idea to store spare tubes on the shelf for long periods of time?" I've used NOS GU-74b's that sat on somebody's shelf for 30 years and they worked fine. So the potential of long shelf life is certainly there with these tubes. I test the spares, in the amp, when I receive them before putting them on the shelf. I see the spares as partly an insurance policy against premature failure of the tubes currently in the amp (which DOES happen), and not just as the next set of finals for the amp. If it was just the latter, I might delay purchase to minimize the time spent on the shelf.

I am an attorney and there are certainly ways to easily indemnify the seller from damages resulting from the negligent acts of the purchaser. I've heard the liability excuse before and it's prevalent in other industries, particularly with vendors in the consumer electronics market. More often than not, it's a great excuse to force the customer to seek assistance through the factory, or through a factory-authorized servicing agent. If an amp manufacturer is so concerned about direct, incidental and consequential damages relating to "user serviceable parts," then they better be more concerned about other factors that can result in damages when using their amplifiers.

When I owned my ACOM 2000A amps, I had several issues relating to faulty tubes during the warranty period. After one year of operation, the switching transistor responsible for the "3-stage" bias circuit had failed with a CE short. In each instance, ACOM walked me though their procedure to restore operation. At the time, they encouraged me to replace the tubes and set bias on my own.

So, unless there's been a significant, unified change in policy among amplifier manufacturers who use the Svetlana 4CX800A, I suspect the overarching reason for hoarding tube inventory is due to product scarcity. The economics dictate that they need to keep an adequate inventory on hand for new product manufacturing as well as to facilitate the fulfillment of warranty repairs. If the supply chain is erratic, they're forced to engage in this behavior.

Joel, and ACOM Group Members
Joel, it is very coincidental that when I saw the issues regarding the 4CX800 tube availability I was going to write you to suggest the very offer you made below. I would be very interested in participating as well.

ACOM Group Members :
Now let me also comment to those reading this and other comments regarding Joel and his former association with towers. I have been a "customer" of Joel's and got my tower through his company. Most satisfactory in all respects. There is a long and somewhat involved story regarding the later problems with tower purchases. The problem with tower delivery lies at the source of the towers - made and broken promises at the source of manufacture unfortunately roll-up the chain to those marketing the product and taking the orders. I can attest that Joel put a lot of personal effort into trying to perform on those orders. Those issues were beyond his control, and you only have to look at the recent history of Tri-Ex ham towers to get some insight into the quagmire of responsibility and commitment that plagued those transactions.

I have the utmost faith in Joel's integrity and his desire to deliver as promised - If quantity buy is the leverage needed to obtain the 4CX800 spares, then I think Joel's offer is about as good as you can get.

Regards,
Norm W4QN

==========

TO OWNERS OF LINEARS USING THE 4CX800A CERAMIC TUBES

That's nice and all but no one is trying to establish a plan to purchase this tube anywhere. Let me roll this one out to everybody.....

I need to know how many linear owners would like to purchase these tubes as my company presently buys and sells electronics worldwide. I will attempt to purchase from Europe a minimum of 100 4CX800A to be sent to my office in the UK. If this is not going to work, I will be asking one of our overseas trading partners to do the purchasing for us in Europe. If there is some kind of game being played as to not allow the US to purchase, this plan will overide that. Also the pricing will be kept to a small percentage over cost if these tubes ever come alive in the future from companies here.

With the above in mind, I need to hear who would be interested in future purchases? Hopefully in two weeks from now I would like to obtain some idea what we're talking about in quanity.

Again, this is just an idea....

I do pretty much what has been described before on the list. Off the top of my head - let them sit 8 hours or so on standby, set the idling current, and then operate with low drive and continue to make several qso's while slowly bringing up the drive. Once I'm operating, I continually monitor temperature of both tubes to make sure they stay fairly close, indicating a good match.

Did anyone read my previous post?

Svetlana 4CX800As are available. They are $434. The company I communicated with is the authorized world-wide distributor. They will ship to the U.S. They have stock and can ship next day. So somebody, please order one!

If you want a cheap 4CX800A, then you have troubles. Those days are gone.

Please, somebody. Buy a tube. Let's see what these guys deliver.

A couple of years ago I bought two brandnew, shining and original
Svetlana 4CX800A for 110 euro; that's about $150 for a pair...

Have a look at Anthony Welsh his site for worldwide distribution and
look for '4CX800A':
http://www.anthonywelsh.com/product_info.php?products_id=94
59,95 UK Pounds a piece. That's about $150.

New GU74b cost about 50-60 euro these days when you visit a radio
fleamarket in Europe. We buy them from East-European sellers. They are
not always on, but somewhere behind the table...

Pse keep us posted as how this goes. Want to see if these are NEW 4CX800A's or NOS GU74B's.
Yes, the price seems reasonable for the tubes. But how come so much to ship? 5 lbs Express is $47.50 and Global Express is $116.00 to ship from NY to Great Britain. Is it that much going the other way?

Here is one issue that I feel is rather important.... When I had a tube failure of one of my pair, it required fitting of several tubes before a good match was found. There were some significant differences between the tubes. With that said, what happens when you order up two tubes from some source only to find out that they are poorly matched? And then your front and rear temps are a way out of whack? At this time, my front and rear tubes are within about 1 to 2 degrees of each other with well matched tubes.

The best solution would be to do a group buy from a reputable source and then have someone match them to be sold in proper pairs. Plus if a bulk shipment was procured from someone as the supplier in England, the shipping costs would be greatly reduced. My suggestion is to have the supplier ship a larger quantity, with a quantity discount applied and then have someone on this side do the matching. Possibly Krassy would be able to provide such a service for a fee. He is the most qualified in my opinion to match the tubes for the Acom.

To owners of linears using the 4CX800A ceramix tubes.....
(first e mail sent February 2 concerning this request)

Tube matching, warranty, availability, price and when the GU74Bs were made, etc, etc, will all be part of the end result BEFORE anything is offered for any consideration to anybody. When we reach the quanity that we believe we need to purchase, the answers to all the questions will be forthcoming.

Right now I am purely exploring our options to purchase in sizeable quanity. At that point all answers to all questions will be obtained and passed along to those showing interest. The purchasing corporation here in the states is utilizing a continued 55-62% off the standard rate for world-wide air freight so shipping is not a problem. Hey, let's see what 100-200 4CX800A tubes are getting us first. We only want to know of your interest ONLY.

Joel,

I'd be interested in a matched pair if that is possible with your offer of a quantity purchase. Again, I might suggest someone as yourself work on the purchase of the tubes, and someone with the proper equipment to measure the tubes in order to make them available as matched sets. The warrantee issues would be a whole new area to consider in the event one of the two tubes in the pair proved to be defective within a short time of use.

From what I have been reading on the reflector over the past week or two, it appears I am not alone in having suffered a tube failure. Therefore it appears the probability of a failure is certainly within a reasonable expectation. At the price of these tubes, we need to have a mechanism in place to deal with such an event. And the second part of this thought pattern is that one doesn't usually discover a problem until the tubes have been installed and used in the amp for quite a few initial hours. So how do we deal with new tubes as spares when we have good working finals and making the switch to the spares requires the change out, recalibration of the voltages, and burn in for about 100 hours before we know they are good spares? If they were offered by a distributor who is authorized by the factory for sales and service, I suspect we would not have too much to be concerned with in terms of a failure. Do you think you would be able to have a warrantee that would be honored by the factory made available?

I know this is all a lot of posed what if's, but I am just throwing it out for thought.

Let me know your thoughts....

2361. Re: GU74B tubes - year?

Yahoo group: acom-list (1999 — 2009)
Date: 2008-02-04 14:39:55 UTC
From: Ken
Topic: 2357 Message: 2361

It appears to me that sending the amp to service center may be the best thing to do. Keep an old boat anchor amp around for a failure of the primary amp. That seems easier than chasing matched tubes and adjusting bias.

From: Hal Kennedy
Topic: 2362 Message: 2362

3-500Zs, 4CX800s and other such tubes do not have rubber seals, they have glass-to-metal seals which will hold up leak-free longer than any of us will. You can buy a used type 01A tube made in 1920 and it still holds its vacuum - it was made nearly 90 years ago with plain-old glass-to-metal seals.

Chinese-made and Russian-made tubes have inferior getter technology compared to US tubes. As such, the getters un-get over time - they return the gas molecules (oxygen is the big concern) they 'got' back into the tube. Restoring the tubes is easy, per the procedure provided here a month ago.

You are not exposed to HV when you replace the tubes or set the bias on an ACOM 2000A. While changing the tube(s) with the cover off, the HV is shorted by one interlock and the AC line is interrupted by another - you are safe. After changing the tube(s), the cover is placed back on with the front panel tilted forward, exposing only the bias pots and low voltage microprocessor components. You can't hurt yourself and liability is not the issue. The procedure is available from ACOM if you ask.

ACOM simply wants to keep people who don't know much from rummaging around inside the amp, particularly while it's under warrantee - a legitimate concern.

2363. ACOM 2000A Failure +5V

Yahoo group: acom-list (1999 — 2009)
Date: 2008-02-04 16:39:54 UTC
From: ea4kd@ea4kd.com
Topic: 2363 Message: 2363

Hello to everybody;

Since last Friday my ACOM 2000A (3 ? years old) gives the next message: "+5V TOO HIGH: 6 V". I have written to ACOM and still waiting for the answer. Following the manual I have verified the voltage at home (220 V.) and the inside ACOM?s selector (240 V.). Everything seems to be correct and I don?t know where must to start look for the problem. Somebody has this problem or heard about this?.

Thanks in advance.

> "Since last Friday my ACOM 2000A (3 ½ years old) gives the next message: "+5V TOO HIGH: 6 V."

Pedro:

I had a similar fault with my 2000A several years ago and in my case, one of the tubes had an open filament. The open filament resulted in the filament supply rail going high, above the normal value and thus the fault.

First, check to ensure than neither 4CX800A filament has opened. Only if you are comfortable in troubleshooting the amp with voltage applied, verify the DC filament voltage value directly at the tube pins.

Standard safety precautions apply when servicing any amplifier with mains connected. If in doubt, leave it to ACOM Service for repair.

Bill,

That assumes the amp says on long enough to generate any heat from the tubes.

In my case, the fault was generated within seconds of powering-up the amp and the amp immediately shut down. If the amp does in fact stay on long enough, I believe the LM35 temp sensors (or what appear to be LM35s) can also be used to sense individual tube temperature. That would certainly provide a good data point.

Pedro, EA4KD"

Then my money is definitely on an open tube filament if the fault is now showing high F voltage. The 2000A is smart enough to quickly check tube parameters shortly after main power is applied. The logic is designed to prevent collateral damage of related circuitry and components in the event of a fault.

As I recall, the logic works so fast that it may not even give the alternate tube any time to warm up at all when an open filament is sensed on one of the two tubes.

Pedro:

I had to go back to your original message. Another suspect is the +5VDC regulator has failed. I had thought the error message was filament V related. But, based on the error text, I would also focus on + 5VDC regulator failure and/or adjustment.

Hi i have an Acom 2000A and IC756 Pro3 and a microkeyer II

And wonder how It can be connected?

now I only have key out connected to the Pro3

but there is also an Pa ptt on the microkeyer is that one to prefer ?

sometimes I get ALC fail when starting to transmit but it goes away when putting the mp in opr again

happens often I think?

Rich,

eBay and PayPal are your friends I suppose? Multiple descriptions on
how to proceed to recondition the NOS tubes in ACOM amps were provided
via this group, so is there anything missing?
I mean if you wait long enough, no NOS tubes left on eBay or against
ridiculous high prices? Have fun with bidding :-)

I run the same combination 756p3, acom 2K, and MK1 and MK2. I run the MK PA PTT out to the ACOM. You can set a PTT delay in the MK. This works to key the amp, then the radio on any keying operation going thru the MK. The microphone keying on SSB must go from the mike to the MK to get this. I think you will be happy with this setup. Any questions like this one might be posted to the microham yahoo group.

Neal,
Thanks for the response. First, I just wanted to know someone is
doing it successfully. Also, an RF feedback problems? I currently use
my Acom with a Icom 756 Pro3. Anything unusual about the connection
or interface?

I appreciate the insight.

2385. Any news regarding tube replacements?

Yahoo group: acom-list (1999 — 2009)

I was wondering if anyone has had any success in obtaining matched pairs of the gu74b/4cx800a tube?

Also There seems to be some misinformation regarding anticipated tube life. I have seen numbers such as: 1500hrs, 3000hrs, 5000hrs, and 10,000hrs. Can anyone provide an accurate life expectancy? Let's say someone using the tubes conservatively and not abusing them as the measure for tube life.

I think there is simply NO WAY TO KNOW since it depends on how you operate the tube. I used to get several years ON 24/7, 365 days per year from Eimac 4CX1000A. I got several years same condx from Eimac 3CX800A7. I expect to get several years from the tubes in the ACOM 2000A with filaments constantly on.

By the time I expect to need replacements I can probably get them from ACOM as a matched set.

All the talk of tube scarcity scared me into buying a
pair of spare finals on eBay, and the tubes arrived
yesterday. I'm not interested in taking apart my amp
just to test the tubes.

Are there any easy checks I can perform to check the
tubes before putting them on the shelf for future use?

Depends on what you feel like testing. Obvious things from a dropped tube like broken filament, bent pins, internal element short can be checked with an ohm-meter and visual inspection. That ends the EASY checks. Even a new good tube might die after a few days so why don't you just store a few spares safely and hope for the best.

Yes, I think you either just pack them away or you fully test them in
the amp. I suggest the latter, after a suitable warmup period,
setting the plate current and then operating at a slowly increasing
drive level over an extended period of QSOs while monitoring the tube
temperatures and watching that they stay within a few degrees of each
other. At that point, you might as well leave them in and make the
original tubes the spares.

2396. Acom 2000A questions

Yahoo group: acom-list (1999 — 2009)
Date: 2008-02-25 11:42:42 UTC
From: Fernando González
Topic: 2396 Message: 2396

Hello,
I just received my brand new Acom 2000A from Vinecom in the UK a week ago. I have been having familiar with its function during this period. Overall I think it´s a impressive amplifier and greatly designed. All values throught the menus seems to be normal acording to the technical supplement here. I got about 1 kw out (key down) driving 30 wts onto it on most every band (slightly more on 40 and 80). I have wired to 240v instead of 220 so getting 1.5Kw out it´s difficult here...je. And now, the question. The use I have made of the linear have been mainly going into the VP6´s pile-ups and quite a few other DX. The temperature of the both tubes remains at a level between 27 to 35 degrees Celsius with 1 kw out. The same more or less on the RTTY pile-ups but with 500 wts this time. Yesterday evening I was calling for DX with my voice keyer for about an hour with 800 wts out. I made a normal call and a few seconds of stand-by. I found out that the temperature went up to 65 to 75 degrees C wich seems to me pretty high. I put my hand over the holes in the top of the amplifier and almost got burned...I wonder if this is normal running just 800 wts. If this would be the way, I bet I couldn´t swtich on the amplifier on the summer time as I don´t have air conditioning here and my radio shack is not a finish sauna. So, what would be a normal temperature reference of this equipment??. Thanks a lot. 73s

Hello Fernando,

I have the single tube version (the
ACOM-1000) and those temperatures seem
reasonable. Prolonged SSB QSOs seem to make it
the hottest. Remember the cooling fan is of
variable speed, and it will run faster as the
temperature rises. The only place I ever feel
heat is above the exhaust hole over the tube. It
cools off very quickly after you stop transmitting.

It is normal for any amplifier to get
warm/hot during transmission, and I don't think
you have anything to be concerned about. There
are owners of the ACOM-2000 here on this list,
and maybe one or two of them can comment on the
exact numbers you mentioned. I really don't think your amp is running too hot.

73/DX Paul VE1DX

Hello Fernando,

I have the single tube version (the
ACOM-1000) and those temperatures seem
reasonable. Prolonged SSB QSOs seem to make it
the hottest. Remember the cooling fan is of
variable speed, and it will run faster as the
temperature rises. The only place I ever feel
heat is above the exhaust hole over the tube. It
cools off very quickly after you stop transmitting.

It is normal for any amplifier to get
warm/hot during transmission, and I don't think
you have anything to be concerned about. There
are owners of the ACOM-2000 here on this list,
and maybe one or two of them can comment on the
exact numbers you mentioned. I really don't think your amp is running too hot.

73/DX Paul VE1DX

Hi Luigi,
The frecuency was 14.243. I was running the amplifier using the auto tune function so that means that I was using the USR settings (not the DEF as recommended by the Manual). SWR was 1:1,4 and reflected power was about 20 wts with 800-900 wts out key down. I got the same reflected power even when I use 1400 wts out. Gracie per la risposta. 73s

Oggetto: [acom-list] Acom 2000A questions

Hello,
I just received my brand new Acom 2000A from Vinecom in the UK a week ago. I have been having familiar with its function during this period. Overall I think it´s a impressive amplifier and greatly designed. All values throught the menus seems to be normal acording to the technical supplement here. I got about 1 kw out (key down) driving 30 wts onto it on most every band (slightly more on 40 and 80). I have wired to 240v instead of 220 so getting 1.5Kw out it´s difficult here...je. And now, the question. The use I have made of the linear have been mainly going into the VP6´s pile-ups and quite a few other DX. The temperature of the both tubes remains at a level between

27 to 35 degrees Celsius with 1 kw out. The same more or less on the RTTY pile-ups but with 500 wts this time. Yesterday evening I was calling for DX with my voice keyer for about an hour with 800 wts out. I made a normal call and a few seconds of stand-by. I found out that the temperature went up to 65 to 75 degrees C wich seems to me pretty high. I put my hand over the holes in the top of the amplifier and almost got burned...I wonder if this is normal running just 800 wts. If this would be the way, I bet I couldn´t swtich on the amplifier on the summer time as I don´t have air conditioning here and my radio shack is not a finish sauna. So, what would be a normal temperature reference of this equipment??. Thanks a lot. 73s

Fernando,
If you have your compression set high, it's almost like full duty cycle.

I suggest returning the amp for that band segment. Perhaps the settings changed and you were mistuned.
My 2000A often goes up to 70C with extended use.
73,
Barry W2UP

Hi Barry,
Thanks for the reply. I don´t think the compression is too high. I´m using a Mark V Field with a PR40 from Heil as a microphone. Mic gain is set at 10 o´clock. Processor is at 12 o´clock. Reading on an average wattmeter and normally talking, the needle moves from 200 to 600 wts when the amp is set for 1 kw. I don´t think it could be overdrived...could it?. 73s

Hi Luigi,
Forgot to mention that I have the extra fan installed but I haven´t hear it running yet. The space around the amp is 15 cms on every side and perhaps 20 cm from the rear of the amp to the wall. Cable is RG-213 mil spec.When the amp is on stand-by for about 10 minutes, the temperature drops at about 30 to 35ºC range. I´m thinking to add an extra fan over the holes to suck the hot air off faster..Will see if I note any improvements. Thinking in a good air conditioning system for the summer (any infos on this are appreciated too). Noted that the amp case is mostly cold during all operation. Grazie mile, Luigi. 73s

I think (1) you need the external additional cooling fan (2) be sure your SWR is okay.

Sounds like the service is closer to RTTY than SSB using the voice keyer constantly. Mine never shows heating like that.

Your temperatures seem pretty normal to me. When I run SSB, with about 1.5 kw output under normal rag chewing with short transmissions of under a minute with a turn over to the other station and then back to transmit, I can see the temperature go up to 80 degrees C pretty easily. I don☐t think this is an issue if you think of it in terms of being only 175 degrees F. This not very hot for ceramic materials at all!

If I recall correctly, Krassy told me this is fine, nothing to worry about. So in your case of using a voice keyer that is running full duty cycle transmissions, even at a reduced output, you are still going to heat the tubes to 80 C. Don☐t worry about it. And don☐t worry about the aux. fan, you don☐t need it.

Subject: Re: [acom-list] Acom 2000A questions

I think (1) you need the external additional cooling fan (2) be sure your SWR is okay.

Sounds like the service is closer to RTTY than SSB using the voice keyer constantly. Mine never shows heating like that.

Subject: [acom-list] Acom 2000A questions

Hello,
I just received my brand new Acom 2000A from Vinecom in the UK a week ago. I have been having familiar with its function during this period. Overall I think it´s a impressive amplifier and greatly designed. All values throught the menus seems to be normal acording to the technical supplement here. I got about 1 kw out (key down) driving 30 wts onto it on most every band (slightly more on 40 and 80). I have wired to 240v instead of 220 so getting 1.5Kw out it´s difficult here...je. And now, the question. The use I have made of the linear have been mainly going into the VP6´s pile-ups and quite a few other DX. The temperature of the both tubes remains at a level between 27 to 35 degrees Celsius with 1 kw out. The same more or less on the RTTY

pile-ups but with 500 wts this time. Yesterday evening I was calling for DX with my voice keyer for about an hour with 800 wts out. I made a normal call and a few seconds of stand-by. I found out that the temperature went up to 65 to 75 degrees C wich seems to me pretty high. I put my hand over the holes in the top of the amplifier and almost got burned...I wonder if this is normal running just 800 wts. If this would be the way, I bet I couldn´t swtich on the amplifier on the summer time as I don´t have air conditioning here and my radio shack is not a finish sauna. So, what would be a normal temperature reference of this equipment??. Thanks a lot. 73s

Luigi
Yes, I would not be concerned about 70-80 deg C. This is what I see running digital voice with only 8-10w drive (but it does have a high crest factor). ACOM's watt meter indicates a ~1kw output at this drive level.

Hi fernando,

For the truth in my case has never reached more than 70 degrees 75 (maximum load up 2 kw) course with this type continued use rtty, sstv or pile up, I believe that you do not have to worry about anything considers that the temperature drops in very fast in any case if you want to use the extra fan.

The report ros is important and also the cable between txrx and acom 2000.

Hi Luigi,
The frecuency was 14.243. I was running the amplifier using the auto tune function so that means that I was using the USR settings (not the DEF as recommended by the Manual). SWR was 1:1,4 and reflected power was about 20 wts with 800-900 wts out key down. I got the same reflected power even when

I use 1400 wts out. Gracie per la risposta. 73s

I never said they were came with a guarantee. It's the first
place I've seen any in months other than eBay. I looked on their web
site 2-3 weeks ago and they had none.

Now there are 3 in stock, and they are sold "as is." Better
than nothing. I still have not seen a place where you can get any
that are gettered (conditioned) and guaranteed. Good luck on finding that.

I have no interest in QRO Parts or any other company that sells
tubes. I just posted that link because some (many?) ACOM users are
looking for spares.

This is what the web page tells us: (a crap translation from Russian into what appears to be English.)

Offered
tubes (Soviet marks as GU-74B!!!!!!!!!!!!!!!) are made in the USSR at 1980-92 on this Svetlana factory, are full analogue and have the best parameters rather
modern Svetlana 4CX800A tubes. These military grade tubes have a
chromium plating, steadier than brilliant nickel plated of modern tubes.

So, these the offered tubes are also the old and dull looking type GU74B tubes, which are the best to buy, price wise and performance wise.

During 1980-1992 no 4cx800a labeled tubes were manufactured by Svetlana. (Russian source information) I personally would not buy tubes produced in year 1992 <> 2000.

Fernando et al,

If you do add the extra fan to suck out the air, my understanding is
that it must have a flow rating considerably higher than the existing fans.
Otherwise, it ends up being a "wind milling prop" which introduces air
flow blockage. The extra noise could be an issue too.

When I had my 2000 even RTTY contesting with no auxiliary fan never
reached the temperatures being quoted. However, the inside air temp in
the shack rarely got above 25C here.

I'd be temped to find out if something is blocking air flow in the unit
experiencing the quoted temperatures. An alternative explanation is
that the blower now shipped with the unit has less air flow than older
units. That is just speculation.

73 de Brian/K3KO

Fernando Gonz?lez wrote:

>Hi Luigi,
>Forgot to mention that I have the extra fan installed but I haven?t hear it running yet. The space around the amp is 15 cms on every side and perhaps 20 cm from the rear of the amp to the wall. Cable is RG-213 mil spec.When the amp is on stand-by for about 10 minutes, the temperature drops at about 30 to 35?C range. I?m thinking to add an extra fan over the holes to suck the hot air off faster..Will see if I note any improvements. Thinking in a good air conditioning system for the summer (any infos on this are appreciated too). Noted that the amp case is mostly cold during all operation. Grazie mile, Luigi. 73s

For those who are desparate looking for a matched pair GU74B's which
are supplied from the ACOM factory: http://www.venhorst.nl/ and go to
ACOM linears. This company claims that they have a stock of GU74B's
direct from ACOM. Not cheap (450 Euro for a matched pair) but from the
ACOM factory. I do not have proof that this is true but I bought my
ACOM Amp from that store and it's a reliable company in my opion.

So just for information to all. Cheers, Ger

Fernando et al,

If you do add the extra fan to suck out the air, my understanding is that it must have a flow rating considerably higher than the existing fans. Otherwise, it ends up being a "wind milling prop" which introduces air flow blockage. The extra noise could be an issue too.

When I had my 2000 even RTTY contesting with no auxiliary fan never reached the temperatures being quoted. However, the inside air temp in the shack rarely got above 25C here.

I'd be temped to find out if something is blocking air flow in the unit experiencing the quoted temperatures. An alternative explanation is that the blower now shipped with the unit has less air flow than older units. That is just speculation.

Hi Callum,
All ideas are welcome. I don´t know what are the valves protection housing. As far as I remember, I got a couple of lables attached with a cable to the tubes chimeneys. It says ¨remove before switch on the amp¨ and this is what I did. I think you´re talking about those labels...aren´t you?. Thanks.

Valve protection housings or tube protection housings are those rubber type inserts placed between the top of the tube and the case. This ensures the tubes remain in place during shipment of the amplifier.

My protectors are a dark gray.

Do not misunderstand and remove the red or white rubber/silicon chimney materials.

Obviously the tube protectors need to be removed prior to use.

It is hard to believe that this level of instruction is required for anyone buying such an expensive amp.

The screen above the tubes (valves) keeps bugs out. LEAVE IN PLACE.
The silicon rubber sleeves around the tubes (valves) directs the air through the fins in the Anode. LEAVE IN PLACE.
The spacers labeled "REMOVE" between the tubes (valves) and the cover are designed to prevent the tubes (valves) from coming out of the socket during shipment. REMOVE THEM. That is why they are loose when you removed the cover to install the Transformer. (The heavy black thing with 4 sets of wires held down by 4 bolts.)

Are you sure you are ready for an amplifier?

Bruce, My XYL went to high school with Clint Eastwood. Must be rubbing off on me. .....you're thinking did I fire 6 shots or only 5 aren't you punk?... He was a good mayor too.

For the guy who left the spacers (tube hold down spacers) in, DON'T TRY RTTY. The only problem is restricted cooling air to the finals. You have been lucky and have a low duty cycle on the finals in your operating mode.

Oh My God!!!! John you could not have said it too soon!

This reminds me of the Corvette meets where some dubber with far too much money on his hands (or the ability to get too much credit) shows up with a new 535 hp Z06 and a pocket protector full of pens and he still cannot see over the steering wheel. As Josie Wales once said, "A man needs to know his limitations", or was it Dirty Harry?

It is hard to believe that this level of instruction is required for anyone buying such an expensive amp.

The screen above the tubes (valves) keeps bugs out. LEAVE IN PLACE.
The silicon rubber sleeves around the tubes (valves) directs the air through the fins in the Anode. LEAVE IN PLACE.
The spacers labeled "REMOVE" between the tubes (valves) and the cover are designed to prevent the tubes (valves) from coming out of the socket during shipment. REMOVE THEM. That is why they are loose when you removed the cover to install the Transformer. (The heavy black thing with 4 sets of wires held down by 4 bolts.)

Are you sure you are ready for an amplifier?

Kees,
When I bought the amp from Krassy and when we used the amp together at V26B he told me to leave the spacers attached to the lid. I have been getting private emails that others have kept the spacers attached. It seems that Acom may have changed the spacers or the need to keep the spacers installed on latter amps.

And yes, I agree that the support from Acom has been very good, even after the warranty expired.

By the way, when I get back from KP2 I hope the GU74B socket has been delivered so I can make up a test fixture to apply heater voltage and check for a cathode-grid short.

I thought the questionable spacers we were talking about were the gray
plastic spacers that rest on the top of the tube fins, not the
cylindrical spacers attached to the lid.

I had to read this thread several times, check my amp, and the box it came in, to understand the misunderstanding that's going on here.

I have a relatively early 2000A, and it was shipped with two gray plastic tubes holding the tubes down. I found them in the box. The tubes are about 2" in diameter and are flared on one end to fit over the rounded skirt below the plate cap. They also have a cutout in the side for the plate tap. Each one has a black rubber cap with a hole in it to allow the tube spacer (see below) to pass through. The cap fits against the top cover. There was a label packed inside the amp that warned to remove the tubes prior to use. These tubes *must* be removed.

The amp also has two tubular plastic spacers screwed to the top cover. These tubes are a little less than 1/2" in diameter and a little over 2" long. Each has a red silicone pad at the bottom that fits into a recess in the plate cap. Without removing the top cover, I can't tell whether the tubes are plastic or ceramic. Either they're ceramic, or the silicone pad prevents the plastic from melting. These tubes should *not* be removed. I've run my amp with them in place for about 7 years. Note that my Alpha 87A has an almost identical set of spacers between the top cover and the tubes. I've run that amp with the tubes in place for over 12 years. My guess is that the spacers ensure the tubes are properly seated during operation.

I don't see how the gray plastic tubes could be left in place without melting or at least showing signs of damage from heat, and they would probably restrict airflow. My guess is that no one on this reflector has left them in place. Those who say they have are probably thinking of the much smaller spacers between the cover and tubes.

Make sense?

Yes, I sure does make sense now! I was talking about the small (1/2" dia)
spacers which are still in my 2000A and the amp works just fine even on RTTY!!

I have never seen the larger spacers as I purchased my amp used.
I guess they were removed by the original owner.

Many Thanks Dick for clearing this up.

Ok, guys. Now I understand. Have to take the top cover off again to put those spacers attached to the top screen back in place...je. It does make sense to me now too. I doubt that someone could leave those big and grey pvc protectors over the tubes as they´re clearly marked as ¨REMOVE BEFORE USE¨. A picture have worth a try. Thanks, great and helpful forum.

2451. Time to summarize the tube and the spacer issue

Yahoo group: acom-list (1999 — 2009)
Date: 2008-02-28 14:56:56 UTC
From: kamarty456
Topic: 2451 Message: 2451

The cover has two exhaust holes with expanded metal [metal screen]
screwed to it. LEAVE IT ON!

Then, you have those narrow white "posts/spacers" attached to the top
cover. They also have a red silicon rubber disc attached to it.
LEAVE IT ON!

You have the red or white silicon rubber chimney wrapped around the
tube. The air flow sensor and the anode connection are going through
the rubber. LEAVE IT ON!

You also HAD inside the tube chimneys a grey plastic tube with maybe
a rubber top loosely placed. The tube has a slot for the anode wire
to pass through it. This is the shipping "tube holder". Most folks
when initiating their amplifier for the first time saw a label that
said "remove this" REMOVE THESE! DO NOT LEAVE THESE IN THE CHIMNEY AS
IT WILL EFFECT THE AIR FLOW AND COOLING!

I think this sums up the discussion. I note when reading all the
comments on this topic it was becoming very confusing. Everyone
identified things differently and it was starting to become chaos.

I hope this post puts everything into perspective.

2452. Key in line and LP-100A watt meter

Yahoo group: acom-list (1999 — 2009)
Date: 2008-02-29 02:31:38 UTC
From: Mel Whitten
Topic: 2452 Message: 2452

I am adding a LP-100A digital vector RF watter meter that includes high SWR protection by opening the PTT (Key in) line. I quesiton if this meter's PTT control is really necessary for the 2000A since it already has this protection. Anyone using this meter and if so did you route the PTT line via the LP-100?
Thanks
Mel, K0PFX

From: Robert Naumann
Topic: 2452 Message: 2454

I don't know how that meter works, but I do know that the Array Solutions Power Master allows you to set specific SWR levels and also at specific power levels - both high and low - which will also open the PTT line when those limits are passed.

If you want to more tightly control what happens, perhaps you would want to use these features.

73,

Bob W5OV

i have both but not wired it into the loop.

I imagine you'd have to set it to above where the 2000a kicks out ???

To a bad 8-1 swr I wonder which would kick open first ?

Mel,

I use the Array Solutions
http://www.arraysolutions.com/Products/powermaster.htm#top%20of%20page
"PowerMaster Station Monitor, VSWR & RF Power Meter," which allows you to
set a VSWR level. Once this level is reached a protection circuit opens,
disabling the amp. The response is immediate and very effective. There
have been a few times where I got in a hurry and failed to change my 4 EL
SteppIR band settings. The Power Meter caught the error and even before my
Acom 2000a shut down, stopped transmission. Very effective, indeed.
Obviously, I try to watch this. But s. happens when you get in a hurry!!

Regards,

Kirk, K6KAR

From: ciccio1973male
Topic: 2457 Message: 2457

Gm om, I am a happy holder of a ACOM1000.
In recent days, I noticed during the transmission also a media power, interference only on TV my house. After checks in my station and in the TV antenna included, I have discovered that the nterferenza came from the TV power supply 220v, I put in a series for dell'acom1000 filter power solving every problem. few of you noticed the same potreblema? In the schematic dell'acom1000 known core/inductance the entrance of a power supply 220v, and perhaps' too low?

Paul,

As has been heavily discussed over the past three weeks, there 'appears' to be a shortage of finals available on the open market. And there is of course always the issue of finding properly matched tubes. I personally am very concerned with the tubes being matched as my first set was not well matched, or should I say became less matched after a short period of time due to one tube working its way to 6 feet under.

My current set is a near ideal match and they run within a degree of so of each other in temperature while being operated.

Now here is an interesting tid bit of information; I was on the air yesterday chatting with a gent who is a radio tech and who works on many different amps. He mentioned to me that the manufacturers are purposely not producing any new stock of GU-74B's so that the current 'glut' of NOS are consumed which will permit them to raise the prices of new stock.... interesting

Bruce,
Thanks for the update. There still appears to be a
lot advertised from every street vendor in the old
USSR. Is it safe to send these guys any money?
Also..... several years back I came across what
appears to be a NOS set of gu74b's. They have been
sitting in my closet until I read about the current
situation. I have taken them out of the dust. They are
untested. Is there any danger to my 2000a to "stick em
in" and fire it up to test?
regards paul w8jn

From: Paul M Dunphy
Topic: 2465 Message: 2465

I have a pair of Svetlana 4CX800As that I got from RF parts about 10-11 months ago. They are in the original boxes and were never plugged into anything. They look like shinny new Eimac tubes except they say Svetlana on them, and the boxes they are in say "St Petersburg, Russia."

I'm willing to part with them as I have a pair of GU-74bs as spares. If anyone is interested, email me privately at "amplifier at ve1dx dot net"

If buying and selling on this list violates it's policy, I
apologize! I got a number of private emails all asking for details
and price. Here are the details:

I dug out the invoice, scanned it in and put it on my web site:

http://www.ve1dx.net/4cx800a_invoice/

It is dated 24 April 2007, and it says "NEW SVETLANA 4CX800A NOT
RUSSIAN SURPLUS S/N 01233, 01224", unit price $349.00 for a total of $698.00.

I'd sell them for what I paid for them plus whatever it costs to
ship them. It cost me $39.00 to have them shipped from California to
here (Nova Scotia.) If anyone is still interested, email me privately at:

amplifier at ve1dx dot net

If you are still interested, I can find out the shipping cost
from the post Office if you give me your address.

2471. Fw: [acom-list] To the owners of linears using the 4CX800A tubes

Yahoo group: acom-list (1999 — 2009)
Date: 2008-03-04 22:11:56 UTC
From: JOEL
Topic: 2471 Message: 2471

----- Original Message -----
From: K2QBV@...
To: acom-list@yahoogroups.com
Sent: Saturday, February 02, 2008 5:51 PM
Subject: [acom-list] To the owners of linears using the 4CX800A ceramic tubes

TO THE OWNERS OF LINEARS USING 4CX800A TUBES.......

On February 2nd and 3rd I posted an e-mail on this reflector concerning the purchase of GU74B ceramic tubes. I outlined a few possibilities mentioned again below and in the February 3rd e-mail I posted.

Here are the results and a few facts as promised;

1, A few responders have mentioned the fact that the GU74B were not being made anymore and have not been manufactured for years. This is correct for the Russian company is allowing all the NOS tubes to be soldout from existing european stock. When stock is at an all time low, they will resume production at a much higher price per tube.

2,There is no current plan to not sell GU74B tubes to the states as some people expressed. Other countries are selling only ones and twos and no quanity of any kind, just theNOS units. Most of the time the tubes sold over the internet, etc are not matched or tested in anyway.

3, GU74B units will be available to the 70+ or so people that have e mailed me on the reflector. Availability is mid-April coming out of Europe and you will be dealing directly with a sizeable radio distributor at that time.

4, Quanity pricing is still being worked on. At this point however, the price per GU74B is approx $200. each (US). Since nothing is coming thru this New York location, shipping will be extra but not a lot of concern.

5, Each GU74B tube will be TESTED and MATCHED before being shipped. The NOS tubes were the last batch before production stopped. Nothing is NEW and manufactured off the last production line.

6, When I get the final acceptance on quanity from the supplier, I will announce the name of the company. At that point, people interested in buying will contact the company directly and provide a credit card directly. The supplier is an established large company and well known in Europe and the UK.

7, I have been informed informed that a lot of tubes recently purchased off the internet or web pages were not up to specs and indeed a gamble. Prices were very high and creeping up each week.

8, I am not involved in the purchasing or selling of these amplifier tubes. I felt that my time spent in the overseas business with international suppliers would help other 4CX800A owners. I am retired and not in the business of selling tubes or anything in that area.

Any questions that you may, have send me an e mail.

Joel, K2QBV in New York
k2qbv@...

TO OWNERS OF LINEARS USING THE 4CX800A CERAMIC TUBES

That's nice and all but no one is trying to establish a plan to purchase this tube anywhere. Let me roll this one out to everybody.....

I need to know how many linear owners would like to purchase these tubes as my company presently buys and sells electronics worldwide. I will attempt to purchase from Europe a minimum of 100 4CX800A to be sent to my office in the UK. If this is not going to work, I will be asking one of our overseas trading partners to do the purchasing for us in Europe. If there is some kind of game being played as to not allow the US to purchase, this plan will overide that. Also the pricing will be kept to a small percentage over cost if these tubes ever come alive in the future from companies here.

With the above in mind, I need to hear who would be interested in future purchases? Hopefully in two weeks from now I would like to obtain some idea what we're talking about in quanity.

Again, this is just an idea....

Joel, K2QBV

I spike with the owner of RF Parts Yesterday

He does not have ANY SVETLANA 4CX800s and does not know when he will receive
any in future
from SVETLANA

2474. Is it safe to purchase

Yahoo group: acom-list (1999 — 2009)
Date: 2008-03-05 14:17:51 UTC
From: Jack Nelson
Topic: 2474 Message: 2474

Good morning all. I'm new to the group and after considerable research, I'm in the market to purchase an Acom 1000, based on the reviews and customer service reports I've read here and in QST.

That being said, after reading the posts on the tube situation, I'm starting to get cold feet. I sure don't want to get an amp and then have problems with service or parts availability.

Your comments, and thanks

Jack K5FSE

ask "the guys" (krassy & will) what a spare would cost with the
purchase of the amp ....

IF they can't provide a spare... what is their offered solution ???

bill (with a matched pair on the shelf)

Jack raises a good point, but I don't think anyone should be deterred from buying an ACOM. or any other 4CX800A/GU-74b based amp, based on the current tube situation.

(1) We were spoiled by the glut of GU-74bs at $100. This was because of a huge surplus after the breakup of the Soviet Union. They are, for the most part, gone.

(2) That price was unrealistic. Look at the cost of similar Eimac tubes (like an 8877 . . . in the $800-$1000 range.)

4CX800A/GU-74b are around and will continue to be, with ACOM, Alpha, QRO and EMTRON having sold literally hundreds of amps containing them. There is a large demand, and sooner or later someone will either stop sitting on the surplus, or begin manufacturing them again. We just won't see $100 spares anymore. Even at $500, compare that to other ceramic/metal tubes of the same calibre. I'd buy an ACOM amp tomorrow if I didn't already have one. It is the best amp ever made, in my opinion.

Paul,

I certainly agree with you. I've had an ACOM2000A for a couple of years and believe it to be the best on the market. Nonetheless, I've decided to sell mine. The only reason I'm selling it is, I have built up another amp centered around a 4CX5000A. I've had the brand new tube and socket for a few years. It took recent retirement to not only get the amp started but finished as well. My new amp uses much of the same type circuitry that ACOM has used. It is also auto tune but built a little more robust than ACOM amps. I have the ACOM2000A listed in QTH.com and it's in new condition. Very little use. It's a good deal for someone!!

Yahoo group: acom-list (1999 — 2009)
Date: 2008-03-08 04:04:15 UTC
From: Jack Nelson
Topic: 2483 Message: 2483

Good evening all. Hopefully I will be a 1000 owner soon. I've seen several postings about weather to use the amp cut off safety feature of these power meters or not. It seems most are not.

My question is, while the LP-100 and the model from Array Solutions are seem really nice and full featured, what do they bring to the table, given all the information that seems to be presented from the 1000? They are not cheap!

Thanks

Jack K5FSE

2486. Contacting Acom

Yahoo group: acom-list (1999 — 2009)
Date: 2008-03-08 16:55:47 UTC
From: Jack Nelson
Topic: 2486 Message: 2486

Good morning all. I'm ready to purchase the 1000, but sure am having problems contacting anyone who wants my money. I've talked to Will's secretary 3 times this last week and he's always out. She took my cell number and said he'd call me. Not yet.

I see from some of the eHam comments, this seems to be a common problem. This surprised me coming from a company that apparently makes such qualify gear.

Any suggestions?

Hi folks

When I read all this messages I would say the ACOM 1000 has LESS problems then the big brother.

Do I interpret this the right way or do I missunderstand something wrong?

I would appreachiate some comment and field-experiences/test/comparison between this 2 PA's.

Can't really answer your question as I've never used a
ACOM-2000A. It will put out double the power of a 1000 and
reportedly auto-tunes on one dit at 40 WPM (that may be an
exaggeration, but it is fast.)

Have had a 1000 for almost a year and it goes every
day. Absolutely zero problems. I can tune it in 5-8 seconds now
that I am used to it. It puts out 1100-1200 watts with the original
tube. Look up what you gain by doubling the power in terms of dB on
the receiving end. That doesn't justify the price difference to me,
although for a contester, the auto-tune feature certainly could. I
don't think you will go wrong with an ACOM amp, whichever model you select.

If you can afford an Acom 2000A, buy one.

It is a much more sophisticated/complex product than the 1000, but
also very well-engineered and reliable.

BTW, it doesn't autotune on one dit - it changes frequency/band (and
antenna with the 2000SW) on one dit and recalls the tune settings. To
freshly autotune the 2000A for a particular band segment and antenna
takes approx. 2-5 seconds.

2490. RE: [acom-list] ACOM 1000 vs 2000

Yahoo group: acom-list (1999 — 2009)
Date: 2008-03-08 19:01:41 UTC
From: Robert Naumann
Topic: 2487 Message: 2490

After owning both, I would say that they are both nearly trouble free.

I had one of the early 2000's and had some connector failures, but once those were repaired, it was fine. In almost 10 years of heavy use in every contest, the only real failure was a vacuum relay.

I owned the 1000 for only about 2 years, and had no trouble with it at all, using it primarily on 6m at maximum output. Very nice.

So, it is reasonable to say that the 1000 has less problems. However, since the 2000 is fully automatic and so much more complex and the 1000 is a manually tuned amp, I think that it makes logical sense also.

Subject: [acom-list] ACOM 1000 vs 2000

Hi folks

When I read all this messages I would say the ACOM 1000 has LESS problems then the big
brother.

Do I interpret this the right way or do I missunderstand something wrong?

I would appreachiate some comment and field-experiences/test/comparison between this 2
PA's.

2491. Re: ACOM 1000 vs 2000

Yahoo group: acom-list (1999 — 2009)
Date: 2008-03-09 07:51:33 UTC
From: Hans Remeeus
Topic: 2487 Message: 2491

Hello Daniel,

I own the 2000A for a couple of years now and the amp is troublefree.
Sometimes he gives a failure and goes exit, but then there is a reason
for it to protect the circuit.

Over the years I changed a lot of rigs, but the Acom 2000A is a
keeper. I also used the Alpha 87A, but IMHO the 2000A is much more
reliable and the service of Stan LZ1IU is excellent; very fast and
detailed replies. The service of Alpha is horrible; they don't answer
e-mail messages at all! Alpha has the name of being the best, but Acom
IS the best!

However; I am still interested in a very good second hand Acom 1000.
Two linear amplifiers are very useful.

When you will need not more that 750 Watt output and you like 'to turn
knobs' it is perhaps wiser to buy the 1000.
Most of the QSO's I use more than 1 kW and I like to have some power
left and not push the linear to its maximum. I like the remote control
and automatic (extremely fast) tuning of the 2000A very very much!

In fact I did not test how the amplifier behaved on 6m after the mod.
It probably can tune up, but the question is if a proper loading
resistance can be achieved. Anyway takes around 10mins to mod/un-mod
it, so for me it is still interesting.

I think it will be VERY difficult to find a smoother solution. Do not
fancy to put any relay switches inside the tank circuit.

Would be nice if someone with a power meter and a spectrum analyzer
could verify the modification.

Easy solution. Set up a CONTEST station. You'll need rig, amp and antennas for every position and every band mode. Your XYL will love it since you'll have to enlarge the house. Maybe buy the adjoining lots.

ralph,
i read the reviews on eham. i assume yours was one
of the negative ones. there is a number of outstanding
reviews and two negative. so the question becomes...
what direction do i go? i have not seen a bad word
about the 9500 since the first two early reviews of
what i understand to be the "prototypes?" i would
appreciate your input!

hey guys, a quick question. My 2000a has been in
storage for a year. I took the plug off of it when I
stored it and did not make note of polarity. as long
as I have the ground wire in proper position, does it
matter which side connection the two hot leads go?
thanks es 73 paul w8jn

From: kamarty456
Topic: 2508 Message: 2508

Just a quick reminder for the new and seasoned Acom users.
Time to clean your air filter!

A clean filter will reduce stress on the tube and electronics, allow the proper amount of air flow to keep the operating temperatures correct.

You should at least inspect the filter 3 times a year, or if in a dusty environment more frequently.

I don't use the amp frequently, so I put a sheet of copy paper over the
tube vents. This prevents dust from getting in that way. In the event
I forget to remove the paper when I turn the amp on, it simply blows off
the top of the amp.

Did it yesterday, Marty! Thanks, however, for the reminder. I had not been doing so regularly until your email to the list of a few months ago. It's one of those things we forget or say we'll do it tomorrow, and as we all know, "tomorrow never comes!"

One addition to this good advice. I added an external filter cut out from a furnace filter. I attach this to the external fan. Once a year I take down the amp off of the shelf in the basement to check out the amp. It is mounted close to eh ceiling so it is out of the way. So far there has been no measurable dust in the amp after 9 years.

N2TK, Tony.

From: kamarty456
Topic: 2508 Message: 2513

I almost do the same thing as Arizona is a dusty place. I have a single sheet of two-ply toilet paper resting over each of the chimney holes. The paper is secured at the edge using tape and some manila file holder paper for stiffness.

This way when the amp fires up the exhaust air pressure blows the toilet paper cover straight up and when the amp shuts down the paper drifts down.

I too have experienced minimal dust inside the amplifier.

I also have added a metal screen prefilter..the type used for muffin fans.

It may seem light a lot of effort to keep the amp clean inside. For those wondering about that, simply put, it's cheaper than having to pay shipping to have the amp serviced from a dust or temperature failure.

2515. GU74b revisited

Yahoo group: acom-list (1999 — 2009)
Date: 2008-03-17 16:53:50 UTC
From: Franki ON5ZO
Topic: 2515 Message: 2515

Dear Tube Experts

This past weekend I was at a major ham fair and found a GU74b for sale. I don't know where the seller came from but he didn't speak any of the languages I tried.
The tube shows a single green strip on the circumference's cooling rib (the ring that consists of many small strips). The seller tried to explain that green means a new (unused) tube and that the color changes when the tube heats.

Is this correct? Does the green mark mean that it's an unused tube?

TNX fr info.

Franki,

I can only tell you that I recently tried to test GU74b tube with a
bright green stripe for a friend.

I first heated it up in an ACOM1000 by letting it run on filiament
voltage only for 4 hours.
Result: Only got 5 ma of idle current instead of 70 ma when tube was at
idle with no RF drive.

The tube was bad.
So does green stripe mean bad?
Can't say. Not enough data.

Hi Frank,

This is the first I've heard of this. All the GU-74bs I've seen have that green strip. I have two "spares" that I tested for 5-7 hours, running them at with enough drive that they were good and hot. The green strip was just as green afterwards as it was before. Perhaps if they were run for days it might fade, but it certainly does not do so in the short term.

I also have a GU-74b in my amp that has almost a year on it, used daily, and the green strip is the same colour as the NOS ones I have. It HAS been run hard in pileups for hours at a time, so it certainly got to operating temperature and stayed there.

I would say that the green strip story was just a sales pitch. I'm no tube expert . . . all I can tell you is what I've observed with the three GU-74bs I have seen.

Since I posted the possibility of getting quanity of GU74B tubes, a few people have written me concerning their bad or really poor experience buying tubes from overseas.

I suggest you wait it out a little and if the tubes appear to not be available I will announce same at that time. I am not involved in any process of purchasing, buying or shipping these tubes but just perform a simple service of locating the tubes with the experience developed over the years in overseas business.

Franki,

I can only tell you that I recently tried to test GU74b tube with a
bright green stripe for a friend.

I first heated it up in an ACOM1000 by letting it run on filiament
voltage only for 4 hours.
Result: Only got 5 ma of idle current instead of 70 ma when tube was at
idle with no RF drive.

The tube was bad.
So does green stripe mean bad?
Can't say. Not enough data.

Dear Tube Experts

This past weekend I was at a major ham fair and found a GU74b for sale. I don't know where the seller came from but he didn't speak any of the languages I tried.
The tube shows a single green strip on the circumference's cooling rib (the ring that consists of many small strips). The seller tried to explain that green means a new (unused) tube and that the color changes when the tube heats.

Is this correct? Does the green mark mean that it's an unused tube?

Hi Franky,

I recently bought a matched pair of GU74B to a store in the Netherlands whom is an Acom distributor. The seller claims they got the tubes directly from the Acom Technical service. I have no way to verify where they came from but I can assure you mines got the green strip you mention on both tubes. I haven´t tested yet so I cannot confirm if they´re good or bad (the seller said they were matched and tested prior shipping). All that I can tell you about the tubes so far is that they look NOS Svetlana tubes and that they were no cheap at all. My opinion is that your tubes are also New Old Stock tubes and the green strips means that they haven´t been used. 73s

Franki,
All Gu74B's that I have seen have a green stripe, except one. I have one that has a black stripe. Also it's date is 2002 (newer than the others) and the anode fins are shiny unlike the dull color of the earlier ones. In addition the printing of the tube info is on the anode fins instead of on the metal just above the ceramic.
Whether the tube is NOS (unused) or has over 6K hours of use there is a green stripe.
So, in my mind with the limited knowledge I have of these GU74B's it seems older tubes have green stripes and newer ones have a black stripe.

By the way is there a simple way to see if the tubes "match"? I just check to see if the temperatures of both tubes are similar at full power out. Presently I have a tube with >6K hours and a tube with <1K hours in the 2000A, The older tube runs about 4 degrees cooler than the newer tube - 57C vs.. 61C at 400W output with RTTY. When I installed the tubes I followed the directions for bias adjustment.

Barry, et al,

What exactly are the criteria for "matching" GU-74bs, of any other tubes for that matter? I assume that the 8 C temperature window means that they are both putting out close to the same power (and hence dissipating the same amount of heat.) My guess is that exhaust temperature is just an indirect way of estimating power output.

Given that they are in parallel, is this simply a matter of trying tube pairs until they draw the same plate current at a given drive (because they both will have the same anode voltage.) I've seen the term "balanced" and "matched" sets thrown around for decades, be it 811As, 572Bs, 3-500Zs and now GU-74bs. Since I have a single tube in the ACOM-1000, I guess it doesn't matter to me. In previous amplifiers that used two or four of the above mentioned glass tubes, if one of them blew, I just replaced it and never worried about balancing or matching. It never caused any problems that I am aware of.

Could someone give a simple description of what a "matched set" is, and if it really matters that much. Does the tolerance of tubes vary so widely from the manufacturers specs that one has to be overly concerned about this? If so, how do the re-sellers put together a "matched" set?

If I recall from a few years ago when Krassy came up to my place with a box of tubes to replace one that had gone south on me; he just plugged in sets of new tubes and mixed and matched them until they were both pulling the same current readings. He then set up all of the various parameters to establish the proper operating ranges of voltages and currents and that was that.

Before I had my one tube failure, both tubes would run within approximately 3 degrees of each other. What tipped me off that something was going wrong was one tube suddenly started running about 12 to 15 degrees warmer than the other, followed by the amp faulting out and shutting down. I told Krassy what it was doing and he said a tube seems to have gone; hence the trip over to my house.

After he found two tubes that aligned well with each other and set up the amp, we ran it. The two new tubes now run within 1 degree of each other, usually almost dead nuts the same. I don't think I have more than 200 hours on my amp and thus far it's doing just fine.

I hope this helps you guys out there..plus for the record, I don't do any contests nor RTTY duty cycles, in other words, I run no more than legal limit at light duty and this has kept me at this type of temperature differential. I only turn on the amp for rough band conditions and never on WARC bands (I just don't like to punch out on a small band segment).

Subject: [acom-list] Question about my spare tubes...

Hello,
I just got a matched pair of GU74B NOS tubes. They´re made in Russia as they got a engraved star with the letters: CCCP marked inside. They´re not SVETLANA and instead they seems to be made by a company wich logo is something like a C inside a circle...I wondering if anyone know who was the company wich made them. Thanks!

Hi Tony,
Oh, yesss...I think you´re right. Another fellow told me in private the same. My confusion was because I didn´t see the word Svetlana any where. THANK YOU, Tony.

Fernando,
I believe the C inside a circle designates the tube was made by Svetlana.

Hello Eduardo,

I had the same question and this is what Stan from Acom wrote me in 2004:

Dear Hans,

Thank you for the question.

The transformer has two 120V-coils with a tap at 100V.

In one connection the upper coil is connected for 100V, and the lower - for 120V, giving a total sum for 220V.

In the other connection the upper coil is connected for 120V, and the lower - for 100V, giving the same total sum for 220V.

Both connections work well. Anyway, the 220V connection 3-4, 6-7, and 8-9-10 (which is printed in Bold on the sticker under the HV transformer) should be preferred since it normally exhibits a slightly less acoustic hum and less stray field under a full load.

In the voltage-conditions you described, a 220V selection is preferable. However, you should be sure that the mains voltage never exceeds 242V (+10% over 220V), which might happen especially during night hours. In such a case you should return to the 240V selection.

I am attaching three files with additional information. Please look at the file "A2000A_Protections.txt", p.6, p.11, and p.12 concerning the heater and mains voltages.

With a 220V selection and a 230V nominal voltage, it would be better to select the "HIGH" selection in the DEF sub-menu (p.12). Please note that you should refresh the antenna matching (via an AUTO TUNE cycle after a LOW-NORMAL-HIGH change) in order to have an effect.

Should you have questions please feel free to contact ACOM again.

Don´t forget that via a submenu on the RCU you can set it for LOW, NORMAL or HIGH with respect to the transformer tap for additional fine tuning.

Kees, PA7TWO occasionally has NOS GU-74Bs for sale. Just thought I would pass along that I just bought two from him - they arrived quickly, were well packed and run great. I aged them in the amp for three hours then went to full power - no problems at all. I still suggest, as does Kees, that tubes from the 80s and early 90s receive more seasoning than I gave these - but I had no problem with them cutting it as short as I thought I could reasonably get away with. They are very well matched as well and run within 2 degrees C of each other (though not sold as a matched pair). TNX Kees!

Hello Hugh,
I got mine from Ron at Vine UK and it´s 10 meters long wich is aprox. 33 ft...I can´t remember its price (was bought a few months ago) but it wasn´t cheap at all I´m affraid.
Hope this help. 73s

A standard computer serial extension cable works just fine. Your local computer supply store should have various lengths, connector genders, etc.

I don't think you need an Acom-provided extension cable. I recently extended my control cable with a standard, off-the-shelf 6 ft M-F DB-9 "straight" RS-232 cable (all nine pins connected straight through -- do *not* use a null modem cable.) So far, I haven't seen any ill effects from using it.

Near as I can tell from the schematic, all communication between the RCU and amp is digital, using RS-232-like technology (the RCU uses the same line drivers as the RS-232 port.) If that's true, no adjustments should be needed for different cable lengths. The conservative limit on the length of RS-232 cables is 50 ft at 9600 baud, and if high-quality cable is used that can be up to about 150 ft. I don't know the baud rate between the RCU and CPU, but it's probably no higher than 19200 baud. I'm sure a 20-foot cable would be no problem at that speed. Probably best to buy shielded cable.

12 ft lengths are standard, and you might be able to find a 24 ft cables. Or, you could combine two 12 ft lengths, or a 12 ft. and 6 ft. Or, you can make your own custom-length extension cable with some multi-wire cable and a couple of DB-9 connectors. You can open the RCU connector shell to see how many conductors are actually required. I don't think it's all nine -- maybe 4 or 5 including signal ground.

Has anyone had any trouble using standard, off-the shelf RS-232 extension cables with the 2000A?

I recently added a length of about 20 feet with a standard cable and it works flawlessly.

2563. BIAS VOLTAGE TOO LOW.

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-03 18:04:38 UTC
From: marcelo@alternex.com.br
Topic: 2557 Message: 2563

Hello guys

During the last WPX, at saturday evening, my Acom 2000 tripped with the message "BIAS VOLTAGE TOO LOW".

I can't start it any anymore. I tried the solutions in the manual: checking the PTT loop and switching off for a while, with little luck. After some 5 seconds into the startup sequence it switches off with this message.

I suspect I had a tube failure. Can it be? How to test? Has anyone had this problem?

Thanks

Marcelo, PY1KN

2564. Bias voltage too low

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-03 21:56:20 UTC
From: Hal Kennedy
Topic: 2564 Message: 2564

Acom amp reflectorAlmost certainly a tube failure - and the most common failure I have seen in these tubes and amps.
The only two ways I know to test for this are to either test by replacing one tube at a time with a known good tube, or to pull the tubes and put on ohmmeter from each grid pin to all other pins and anode on the highest scale you have (megohms). If you can read any resistance at all you have a bad tube - but a bad tube will sometimes pass this test.

This is not an accusation of any kind, but this failure seems to show up commonly one of two ways:
- Tubes bought out of the Ukraine - which are all junk as best I can determine and are not NOS - the soviets never warehoused tubes in the Ukraine. Tubes from the Ukraine are pulls from old gear and are used,and often arrive with the grids already damaged.
- Routinely going beyond 1500W output. Even a little.

Here is a test I suggest everyone who owns a 2000A run for their own satisfaction - I think I have mentioned this before here:

Auto tune the amp into a nice 50 ohm dummy load. While set to measure control grid current, turn up the drive and watch what happens. Then do it over again while watching screen grid current. Notice, up to 1500W output both currents are essentially zero. Also notice as you move above 1500W output the grid currents take off - fast - into the destructive range of the tubes. This is the one area where the amp will not fault-out either. Between 1500 and 2000W output the amp will just let you slowly melt the grids. Above 2KW someplace the amp will fault-out on overdrive - but you are damaging the tubes before you hit that point.

Topic: 2566 Message: 2566

Good evening. I have a new 1000, that just had power applied last night. I'm using it with a Pro3 and a Palstar AT-Auto Tuner with the KL circuitry. This is basically QRO circuitry that allows the tuner to keep the rig and amp from transmitting while it's doing it's tuning thing.

My problem is that I've set the P3 for 25w, and that is what shows on the tuner's meter, but while the 1000 has the green op light on, the amp is not doing anything while the rig is transmitting...just like it's still in standby.

When the green op light is on, that means the amp in in the Operate, readyy to go mode, correct?

I think my problem is in the configuration of the QRO keyline on the tuner.

What is the stupid newbie error I'm making?

Jeff,

I don't know what the "Palstar AT-Auto Tuner with the KL
circuitry" is doing for you, but I have exactly the same setup
(PROIII and an ACOM-1000.) I key the amp directly from the PROIII
and have been doing so for almost a year. Works fine. I'd eliminate
the Palstar for now until you verify the rig can key the amp
properly, and then put it back if you still feel it is
necessary. (And yes, with the green LED on it is in operate mode and
should "amplify" when RF is applied and the amp is keyed.)

Hello Hal

Thanks for the information.

I believe the cause for the failure was that I transmitted for hours at the wrong antenna, without noticing it. A 40m dipole on 15m. Maybe the SRW was not high enough to trip the protection, but enought to damage the tubes in the long run.

I got very upset at myself when I noticed it, too late. I think a automatic antenna switching would pay itself, hihi.

2572. gain too low /mains fuse blowing

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-04 13:14:24 UTC
From: LA7SL Nils P. Pedersen
Topic: 2572 Message: 2572

A serious question here :
Did anybody solve the "gain too low" problem with the 2000A ?
I have exactly the same thing happening here. Output drops to 5-600 watts
and the amp protects with this message. Sometimes it helps to retune the segment,-
sometimes not. If not, restart 2-3 times usually solves it... but i cannot find
the real problem. Lately the amp has on two occasions blown the main fuse
at the end of the startup cycle. Replacing the fuse and restarting solved the problem
for several weeks. Power normal and all readings normal until next time it happened.
Same routine and it is still normal, but with the occasional "low gain" trip...
Antennas are checked and excluded as a reason for this. The fault is antenna and band
independent. All monobanders here. I think I may have had a couple of flashovers in the
tubes
(fuse blowing) but I am not sure if this is in any way connected to the periodic "low gain"
problem. Anybody ??

Hi !
Not really,,,,
Sounds very strange to me..
I can think of only three possibilities.
1. internal wiring / relay problems
2. sensor problems
3 Software problems.
details:
1 : There may be a wiring problem or a relay (?) problem that causes the heaters to get current before they should. Could be caused by a faulty relay, faulty relay wiring/control or a short somewhere.
2 for the CPU to know when things are happening and what is happening it needs to receive control signals from appropriate points in the amp.
If it erronously receives voltage/current present from the heater circuit it " thinks" there is a problem when there is not.
3. CPU has a problem and interprets the situation erronously.

As you can see these three points actually includes a lot of circuitry like the RF-deck the power supply the interface and the CPU !! My advice : Call Acom !
Sorry Paul...

2575. Gain too low/blown fuses

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-04 20:04:22 UTC
From: Hal Kennedy
Topic: 2575 Message: 2575

Hi Bob, sounds like a bad tube to me :-)

In all seriousness, gain too low is typically a bad tube, and having the fault intermittently is very consistent with a failed grid. However, I have never encountered blown mains fuses before, so I'm not sure what to make of that.

A hard short of a control grid to either the cathode or the screen grid of either tube will remove all grid bias, and at that point the tubes both go to full conduction and essentially short the plate supply, even if you are in standby. I suspect that will blow the mains fuses, since the protection circuits simply put you in standby and none of them remove the anode voltage - its always on the tubes. I'm guessing this particular failure will reveal itself just by putting an ohm meter on the tubes.

Grid troubles in these tubes can cause some very odd behaviors. My first-ever failed tube produced the following symptoms: The amp ran normally in every respect except while it used to auto-tune up to a 3:1 SWR, after a while it would only auto-tune up to about 2:1. Beyond that, auto-tune would yield an "SWR too high" error message, even though the SWR was only 2:1 and the amp continued to run great into 2:1 - it just would not auto-tune anymore. As months went by it got worse and worse, until the amp would not auto-tune even into a dummy load - but you could manual tune it and it ran great, including normal gain, full output, and good matching between the tube temperatures. Turned out to be a bad tube. I have no idea what was wrong with that tube, but it taught me to suspect tubes before anything else.

2579. Not changing Bands

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-06 14:22:31 UTC
From: barbiekenw
Topic: 2579 Message: 2579

My ACOM-2000 seems to have a problem.

1. My ant shows SWR 1.1 on 14.010 Mhz (MFJ-259B).
2. Amp warms up, I put it in the apply drive mode so it can tune to the antenna
3. I apply 15 watts of drive on 14.010 Mhz.
4. The autotuner works for about 7-8 seconds, and I get a message "Check VSWR, Please remove drive".
5. The display never showed SWR nor forward power in its LEDs.
6. I look to see that it is sitting in 3.95 - 4 MZH segment.
7. I repeat on other bands, and it attempts to tune, but never moves off of 3.95 - 4 Mhz segment.
8. If I touch my CW key on 14 Mhz with drive set to correct value, the amp just seems to ignore me. I think that results from the drive being so far from 3.9 Mhz.

No I do not have split enabled on the transceiver.
Any ideas?

Ken

From: Ken
Topic: 2579 Message: 2581

It is in the autotune mode - asm indicated by the display.

If I manually change bands with the UP/DOWN arrows then push ENT, everything tunes and looks normal.

But when I change bands with the exciter, and hit a pulse, the amp does not follow. I have to manually move it to the new band.

Is there some command somewhere that puts the amp into a condition of not making band changes with the exciter?

Ken

Good morning all

Trevor asked a good question. The Acom amp provides a means of monitoring all kind of parameters, such as exhaust temperature (just one example), but I see nothing in the manual about what the limits are, in other words how do I know if it is almost getting too hot?

No schematics with my amplifier either - is this normal ?

Regards

John G4ZTR

One of the nice features which makes this AMP so easy to tune and load and operation is a breeze, is the fact that when the typical values for the GU74B are exceeds, the AMP protect itselfs: above 600mA anode current you will get a warning first and after that it shut's down, when grid current exceeds, it shut down. Same applies for drive, VSWR, temperature etc. etc.
I did operate once with full output and the coax cable (connector) broke during transmission.
The AMP was immidiatly shut itself down: I was very impressed!

I'm not saying that the Acom 1000 can not be damaged but under normal circumstances it can not break so I think there is not much to be afraid of.

GL with your AMP and have fun. 73's Ger

Sounds like the freq counter in the amp may be kaput?

You might a master reset of the amp (note, your hours used memory will be lost).

Or you could call Krassy or Will. Sometimes they can give you some troubleshooting tips and help you avert shipping the amp back to them.

Good luck

Great suggestion, and one that I have not done!

I will try the master reset, and let you know.
I have the amp ready to ship back, but I will take it out of the box and try that. I sure hope that works!

Dan,
I would say you saved me $80 shipping! The computer had not been reset in 3 years of use.
I did the ESC-ROCKER SWITCH reset. The amp is now tracking OK.
The problem was intermittent, so I will let everyone know if it returns.

2591. TO THE OWNERS OF LINEARS USING THE GU74B/4CX800A CERAMIC TUBES

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-08 20:18:29 UTC
From: JOEL
Topic: 2591 Message: 2591

As promised in my previous postings, I finally have the opportunity to tell you about a distributor that will sell the Acom GU74B tube in quanity. I had requested sometime ago on this Acom list an indication of whom would be interested in purchasing these tubes and to please e mail me your sincere interest. So far, I have received indications that 81 plus tubes are requested. I will be responding directly to each e mail that had requested purchasing the tube(s). When you receive my email, it is up to you to contact the distributor DIRECTLY and make financial arrangement with them. Please keep this purchasing infomation to yourself as the GU74B tube is limited and just the e mails received for now with have their order filled from present stock. When more tubes past what is in inventory is required there is no guarantee of pricing. All emails received by me will be fowarded to distributor handling your transaction. Remember, you have to contact them directly.

To be fair and fully understand what is being sold , I am listing below the specifications for the GU74B tube. This will include all the infomation about the tube, prices, etc., etc....

-The Russian GU74B have been tested by a tube tester designed just for this tube. Tests consists of varying G1 volts under a constant G2 and plate volts. This according to the distributor allows the tube to be tested in dynamic conditions for four steps of G1 volts. The four steps of plate current resulting will be logged against the tube number and matched pairs.

-Cost of each GU74B is $200.and MATCHED PAIRS at $450. All tubes are tested and a certificate of compliance comes with each tube. The tubes are not tested in an amplifier but for an additional $25 tube,this will be done upon request.

-Cost of shipping with insurance will be just about $60. Two tubes or up to six tubes can have a weight of approx 2 lbs.

-There is a warranty on each tube for oneyear. Bad tubes must be returned to the sender for replacement. The buyer pays for shipping back to the company and the company will return the replacement tube at no charge.

-The distributor will take credit cards as he will discuss this with you upon contacting him.

-The year of manufacture of the GU74B is 1987 or 1988. Accordingly, these were the "good years" and no new tube is being manufactured today. If tubes were made today, I have been informed that the price will jump up three fold plus.

If you e mailed me with a previous request, by next week you will receive an e mail with instructions on purchasing the GU74B Acom tube. If you want to get on the tube list for the above, send an e mail requesting same to K2QBV@...

Too much optimism. Today it is not tracking again.

I guess its time for that fateful UPS ride to Massachusetts.
BTW, the master reset of the computer is on page 23 paragraph 5-7.

Topic: 2575 Message: 2596

Thanks to everybody that came back on this subject ! Nothing is found here
that can
explain the blown fuse (apart from a possible tube failure). No burn marks
and no faulty
insulation or suspect capacitors. New tubes are on their way. They were, by
the way, not so
easy to find. At least not at a reasonable price or quality....

20:04:22 +0000Subject: [acom-list] Gain too low/blown fuses

Hi Bob, sounds like a bad tube to me :-)In all seriousness, gain too low is
typically a bad tube, and having thefault intermittently is very consistent
with a failed grid. However, Ihave never encountered blown mains fuses
before, so I'm not sure what tomake of that. A hard short of a control grid
to either the cathode or the screen gridof either tube will remove all grid
bias, and at that point the tubesboth go to full conduction and essentially
short the plate supply, evenif you are in standby. I suspect that will blow
the mains fuses, sincethe protection circuits simply put you in standby and
none of themremove the anode voltage - its always on the tubes. I'm guessing
thisparticular failure will reveal itself just by putting an ohm meter onthe
tubes.Grid troubles in these tubes can cause some very odd behaviors.
Myfirst-ever failed tube produced the following symptoms: The amp
rannormally in every respect except while it used to auto-tune up to a
3:1SWR, after a while it would only auto-tune up to about 2:1. Beyondthat,
auto-tune would yield an "SWR too high" error message, even thoughthe SWR
was only 2:1 and the amp continued to run great into 2:1 - itjust would not
auto-tune anymore. As months went by it got worse andworse, until the amp
would not auto-tune even into a dummy load - butyou could manual tune it and
it ran great, including normal gain, fulloutput, and good matching between
the tube temperatures. Turned out tobe a bad tube. I have no idea what was
wrong with that tube, but ittaught me to suspect tubes before anything
else.73 Hal N4GG[Non-text portions of this message have been removed]

I do not know really... It was real hard work to locate a supplier
that could sell me those tubes... Some said yes..and nothing
happened . Most of them told me it was no more produced.. Acom OOD
in Bulgaria told me they were still manufactured, but could not tell
me where to buy them. Massachusets decided to just forward my email
to Bulgaria.
I now have a nice collection of very confusing mail... Latest
development is that Mr. Vassilev of Acom OOD will contact me early
next week. Hopefully to clear up all this confusion. I do not forward
personal mail to a list, but anybody is free to contact me directly
if they are confused like I am...The website www.acom-tubes.com
is registered to a UK electronic components supplier. According to
Internic the server is located in the UK. The very same company has
an online tube shop. They do NOT sell the 4CX800A / GU74B :-)
regards

TO ON4IQ......

Perhaps..... Try and buy some GU74B tubes and at what price if you do find a few. They will be produced again sometime in the far future and at a hugh price. Hope this answers your question.

I have nothing to do with the supplier other than trying to help other ACOM owners than can not locate a stable stocking supplier for the GU74B ACOM tubes.

Joel

I recently bought GU74's for 80 euros a piece for the acom2000 amp,
from a former east german station.

But once again the 4CX800 are still in svetlana's catalog so it was
not a question but a simple statement.

I suggest people conteact svetlana to see wether the tubes are in
production or not.

ps severlar russian station offer the GU74 in small quantities,
thought the reliability is not assured.

I have tried to contact Svetlana both via the email adress at the site
www.svetlana-tubes.com
(info@...) and directly via svetlana@... . The latter adress is the
one given as direct mail to svetlana jsc in St. Petersburg. I asked two simple queations :
1. Where can I as an individual purchase new 4CX800A / GU74B ?
2. Is the 4CX800A / GU74B currently in production or has it been lately ?

Anwers ? Not ANY response at all !!
And what Svetlana catalog are you taking about ??

Subject: [acom-list] Re: 4CX800

Joel

I recently bought GU74's for 80 euros a piece for the acom2000 amp,
from a former east german station.

But once again the 4CX800 are still in svetlana's catalog so it was
not a question but a simple statement.

I suggest people conteact svetlana to see wether the tubes are in
production or not.

ps severlar russian station offer the GU74 in small quantities,
thought the reliability is not assured.

We all were through this several months ago, and came to the same conclusion. Svetlana 4CX800As are NOT available anymore. No one can contact Svetlana and get an answer. Some claim they have a catalog, or can get 4CX800As. I have seen no evidence of this in the past year. I had two Svetlana 4CX800As that I got from RF Parts last year that I sold about 6 weeks ago. RF Parts no longer has any in stock and can't say when/if they will get any, or how expensive they will be if they ever do.

As far as I can tell, the ONLY source of spare tubes for ACOM amplifiers are NOS GU-74bs from the former Soviet Union. GU-74bs we never made for amateur or commercial use. They are a rugged tube, both from a physical and electrical standpoint. They were made for use in Soviet Union military equipment. Any that are available are at least NOS 15+ years old. NOS, as in New Old Stock. It is my assumption that Svetlana made the 4CX800A as a commercial/amateur alternative to the surplus GU-74bs. I further am guessing that with the glut of $100 NOS GU-74bs floating around for 10 years, Svetlana were finding it hard to sell 4CX800As at $300-$400 and ceased production. I can't prove this, but it seems to be the case.

Now that NOS GU-74bs are getting harder to find and more expensive, we may see Svetlana or someone else start making a 4CX800A again.

Please understand that the 4CX800A and the GU-74b are not the same tube and were not made in the same factories. One is a commercial/amateur product and the other is a rugged military tube. They are electrically compatible and can be interchanged in our amplifiers. Which is better? I don't know. A NEW GU-74b would be tougher. You can't get a NEW GU-74b. A NEW 4CX800A would be far

less likely to suffer from leakage, etc than a NOS GU-74b that's been sitting around for 20 years. The dilemma is; where do you get either one? No one seems to be able to consistently answer this question.

Just mailed the GU74B list overseas to fill orders. I do not know if you're on the list to receive a tube(s). In any event this is the FIRST source I knew of. Another one is to follow but I'm sure you want the tubes tested and guaranteed. With such a good warranty from Acom I'm sure you want need another tube for a while.

Unless you plan to purchase a lot of GU74B tubes manufactures will ignore your request as per what's was touched in this e mail by LA7SL.

Hi,

in 2003, just before a visit to St.Petersburg I asked Svetlana
if they sell small quantities of the 4CX800 locally.
There answer was
"no, they do not presently produce 4CX800s and do not sell any locally
BUT IF I WOULD PLACE AN ORDER FOR AT LEAST 1000 (or so) TUBES
they would lay on a production run".

I've been watching thread for some time...

I have a couple of simple questions:

1. Acom continues to sell amplifiers that use these tubes. Where are they getting them from? If they are so rare/unreliable, you'd think they would switch the design to a different tube.
2. If Acom has tubes, why don't you buy from them?

Hello Gerry Hull,

I am sure Acom purchased a lot of GU74B tubes when they could buy quanity and they were indeed tested. Today however, the tubes are rare according to many reports duds have been purchased by many people as you've seen on this reflector.

Regarding your question of being "unreliable". I don't think people have seen this occur ONCE the tube was completely tested. Many duds were tossed away that made a reappearance from a junk pile in Europe.

The second question you asked was why one doesn't purchase the GU74B from Acom. First of all, I personally have my spare tubes tucked away and my Acom 2000 only has 349 hours on the read out. People have tried to purchase from Acom and they stated they are not in ther tube business and can not help them out. Listening to the owners of the Acom amps, it appears they are getting 6,000+ hours unless they "open it up" all the way. I am sure the tubes Acom has are being kept for new amps and warrany replacements as the amps are selling real fast. What's really out there? An amplifier company that can't make more than one or two model 9500 amps a month or a company located 10,000 away down under. We all know what's really going to happen. When the NOS tubes are gone, the manufacturer will make them again and sell these at $400 PLUS. Amplifiers are out there and cost a lot of money and will in the future indeed need a tube or two.

I hope the above answers your questions. Personally I am not buying the GU74B but just trying to help sort things out as to where to purchase it.

Joel, K2QBV

From: sam_w4pk
Topic: 2609 Message: 2609

I get a message on my 2000A control panel saying "HEATER VOLTAGE TOO LOW : 0.00V". I suspect that the failure is in the monitoring circuitry somewhere rather than an actual heater failure. Before I tear into the amplifier, has anybody ever encountered this message? Is it in fact a true failure of the source of the heater voltage, or is it an A/D problem? What makes me suspicious is the 0.00V reading.

Sam,

Could it be that you have an early amp (first 2 years I believe) that has
the
filament connectors that can ultimately heat and burn and maybe your
filament voltage is just low
and amp is somehow reporting 0.0 instead of the actual low voltage ???
(You could have 2 problems !)
You could at least pop the to cover
and operate the amp with High Voltage precautions and make a filament
voltage "confirmation" measurement. Please contact ACOM to confirm what the
High Voltage precautions are before getting into the amp !!!!

2611. Heater Voltage Too low

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-16 18:08:54 UTC
From: Hal Kennedy
Topic: 2611 Message: 2611

Acom amp reflectorIf its an early S/N you probably have burned filament connectors - a common problem. There are three connectors in the filament lines if I remember right - although its been a long time and it could be only two. There is a connector at the power supply board, and a connector inside the RF deck you can get to by pulling off the bottom plate. Inspect these carefully. Some folks have just jumped the connectors out - and if you have the one inside the RF deck burned I would jump that one out for sure - you literally have to disassemble the whole amp to get at it and replace it. The one on the power supply board is easy to replace. ACOM changed to a properly rated part after a year or two of production.

>What does the akronym NOS for GU74B tubes mean ?

A number of others have already answered. I will expand a bit. It does indeed stand for "New Old Stock", which sound like a contradiction. It means that it is New as in never used, but Old as in it has been sitting around for a long time. GU-74bs have not been manufactured since the early 1990s, so any that you fine are likely 17-20 years old. They likely never were plugged into anything after leaving the factory, and many are in their original sealed packages. The problem is, how well do they "age" sitting on the shelf? Did they lose any of their vacuum? Did and gas leach out of the materials it is made of (there is a getter inside of tubes to absorb this gas, but the tube needs to be powered on for the getter to work.)

These are reasons why NOS tubes can be suspect and why new tubes are preferred. If a NOS tube is slowly conditioned by apply incremental levels of heater current and plate voltage over many hours, it almost certainly will be as good as a new tube. The trouble is, most of us do not have the equipment to condition a NOS tube, so we have to take a chance that it will be OK.

NOS is used to refer to anything that sat on a shelf or in a warehouse for years. It is not unique to transmitting tubes. Could very well be used with car parts or anything else.

Not being familiar with the term, I asked the same question on another list about 18 months ago. This after being licensed over 22 years and changing tubes in an AL-1500, a TenTec Centurion, a Dentron Clipperton-L, a Drake L4B, an Ameritron 811H and most recently my ACOM-1000. Somehow I survived the high voltage, and I never heard the acronym "NOS" until about a year and a half ago. When it started getting tossed around with respect to GU-74bs, I asked what it meant. We all are still learning! :-)

>We all are still learning! :-)

Indeed. This past week I received an email regarding our beloved tube:

There is so much misinformation about the GU74B, it is quite amazing.
The green strip is not there to indicate a new tube. Look carefully. It
is painted opposite the gap in the tube pins.The green stripe is simply
to orient the tube correctly when inserting it in the socket!

So far for "green means new"... I admit: I've never opened the amp or took
the tube out of its socket. I took the cover off a few months ago. If it
ain't broken...
Also, to quote my teacher Digital Electronics: "More than 12V you say? I
ain't touching that stuff!".

Hi Frank.
My 2002 GU74B's have a black stripe. Do you think that makes them newer or older than the green stripe? :-)

Thanks for all the responses! This is indeed an early unit (2000 vintage) which I had bought used from fellow PVRCer Brian K3KO several years ago. I first tried looking at the filament power connectors on the bottom board in front of the power transformer. I did it the hard way the first time by removing each board in the stack one at a time to get to the bottom one. But its connectors looked okay, so I just put contact lub on them and put it back together. Still no go.

Then I saw Hal N4GG's suggestion to check the connector in the RF deck. Sure enough, it was discolored. I removed the connector and soldered the wires directly to the board. And it worked!

But in the process of fixing this I screwed something else up. Now when I slowly apply drive I get reflected power showing on the ACOM remote meter and a msg saying to remove power. This occurs at very low power inputs, 10-20W and it trips with about 50W reflected showing on the meter. I get the same thing with AUTOTUNE. But when the amp is in the standby mode I get 1:1 SWR through the amp.

I have worked on this amp enough for a while. It is time to go hit some golf balls! When I get my act back together I will tear it all apart (for the third time) and try to troubleshoot what I had done wrong.

Again, thanks for all the suggestions!

Indeed, we are all learning every single day.

The Green colored stripe on the GU74B:

I've seen very light and very dark green colored stripes on many GU74B tubes in the past years. So, in other words, the color intensity (light or dark Green) does not tell us much BUT... if the tube is heated some some hours, this Green stripe is colored brown. If heated for a long long time the stripe gets very dark Brown / Black. Whether or not this color change was intended to take place or just to indicate the PINs > socket, well it is a handy "tool" in most cases to determine the state of the tube.
Now the bottle neck; I've seen Brown (almost Black) stripes while the tube was packaged with certificate in sealed and carton boxed, really a new tune. Tube was even shiny not dull. So, it looks like the Svetlana factory sometimes had troubles 'mixing' the correct color green.

If one would like to see some pictures of the different colored GU74Bs, contact me on my e-mail address. QRZ.com e-mail address is OK.
If one need a spare GU74B, you can contact me as well. NO matched tubes available at the moment, only single NOS tubes.

2628. 2000A Failed heater voltage - fixed but.....

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-19 18:00:08 UTC
From: sam_w4pk
Topic: 2628 Message: 2628

After being given the hint that my problem was at the connector in the tube deck, I was able to successfuly repair this problem by soldering the filament leads directly to the interface board. This is on an amplifier of year 2ooo vintage, and the connector can be gotten to by turning the amplifier on its side and removing the access plate on the underneath of the tube deck.

But now I get a message saying to remove power when I increase my input up to just 10-20W. 50W is showing on the reflected power when it trips, even though I have the amplifier hooked up to a dummy load. When the amp is in the standby mode, the exciter shows that indeed there is the dummy load connected. Also, the exciter continues to show 1:1 when the amplifier goes into the alarm state.

All voltages and currents are normal when in the OPR state with no drive applied. When applying with what must be a couple of watts of drive or so, the amplifier does detect the drive, and the bias voltage switches from -130V to -48V. However, the tube current jumps from 0 to 0.39A! All other voltages and currents remain normal. So it appears that I may not be getting that -48V to the tubes, although apparently the -130V is present when no drive is applied as in that state it cuts off the tubes completely.

Physically, I can find no apparent loose wires in the tube deck area, and I measure high impedance on the grids to ground. Also, I rechecked the three Molex connectors in the PA deck area to confirm that they are properly installed. I am sure that whatever I did will be obvious once I find it, but for the life of me I cannot put my finger on it.

I do have a copy of the ACOM2000A Technical Supplement, but it is incomplete in that there are no schematics involving the RF circuitry and particularly how the bias control is routed and controlled.

My question to the reflector is that does anyone have a more complete diagram (RF and module interconnect) of this amplifier? Has anyone ever encountered this problem before? Any hints?

I will send you a PDF file of schematics, (In a separate e-mail Sam)
if anyone else needs a copy let me know

I have had this PDF file a few years so I think it will be accurate for
your early model but can not vouch for newer (last 3 or 4 year ACOM 2000)

If this doesn't help, contact Will or Krassy at ACOM Monday)

Sounds like it's going into an VHF oscillation. That would explain
both plate current and high swr trip.

Look at tube socket base to see that all bypass caps are in place.

Any indication (via temp or filiament current) that one tube is bad?

A few years ago I bought an Acom 2000A at Cor Rietdijk PE1ALV. He has
excellent service!!

Cor is also selling new GU-74b for 85 euro excl. shipping and he sells
worldwide. Cor is an official Acom dealer.

GU-74b socket for 45 euro, socket including teflon chimney for 55 euro.

You can reach Cor at pe1alv.acompower@...

Hello again Brian, both tubes are good (get rapidly-increasing temperature readings for both tubes). It could be a VHF oscillation, but it more likely to have been caused by something I have done (like, didn't hook up the bias circuit when I reassembled the LV supply.). Besides, the plate current goes back to 0 when I remove drive. I just got a complete set of schematics from Dennis N6KI so I am going to take my time and analyze what could have caused it. I am going to have to put it aside for now as Judy and I are preparing to go on our semi-annual vacation trip to Hilton Head.

I never looked at the temp , differences between the icom 78 & k3
as a driver.

Works fine , as expected. Keyed without any loop or agc.

I have the K3 and ACOM 2000A running here at N3RS. The conbination is working well and plans to change from FT-1000MP's to K3's for each operating positions are in process. I have used the K3 primarilly on CW, but even on SSB the combination is FB.

Subject: [acom-list] K3 with Acom 1000 or Acom 2000A??

Hello K3 & Acom group,

Someone who has this combination functional?

Reviews and reports are very welcome.

Thanks!

2641. ACOM-1000 on 50-MHz

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-21 19:01:21 UTC
From: Paul M Dunphy
Topic: 2641 Message: 2641

Are any of the list members using an ACOM-1000 on 6M? I just put up a 6M beam, and it's flat on 50.125 MHz (1.0 to 1 VSWR.) If I drive the amp any higher than about 600 watts output it says and "OVERHEATIG" and "REDUCE DRIVE." (Exhaust temperature = 38 C.) I had the same problem with a different feedline and a dipole, so I strongly suspect it's the amp, not the antenna/coax. 600 watts is fine, but it *is* rated at 1000. It works fine on all the other bands from 160M through 10M. Seems to tune fine on 50-MHz, just doesn't like to be driven over 600 watts (drive from the exciter is 26 watts to get 600 watts out according to the ACOM front pael display.)

Just curious if anyone else has encountered this.

Paul,

I've used mine on numerous occassions at full output (1000w) without any problems. On Dxpeditions, in addition to the usual modes, I've used it for EME and MS and my Dxpedition partner Dave K4SV has used his extensively on RTTY at high power levels without a hiccup. We tend to drop the power a bit if the duty cycle is high but only enough to treat the tube with respect. I've never seen this particular error message.

Both our amps gave seen a lot of action and have never missed a beat.

Was (Exhaust temperature = 38 C.) a typo? The air temp at Clipperton was higher than that during the day...

Neil

Paul,

I'm getting 1050 Watt exactly on 6 meter. The max output is a bit lower then on HF (10-160m) but >1000W on six is no problem with about 30W drive. 600W however is about 2 Db lower then 1050W out.
I should contact Acom about this.
I assume you tuned the Load Cap in the middle and Ia = approx between 600 - 700mA. What is the RF power gain indicating?

Best regards, Ger PE1CZG

Thanks, Ger . . . the plate current is 580 mA, and the RF power gain is 14.0 dB (14 dB seems a bit higher that the HF bands . . . they are around 12 as I recall.) VA7DX asked if the exhaust temperature was a typo. No it is 38 C. (obviously will rise if I operate any length of time.) I gave it to indicate at least the air flow doesn't seem overly hot, and the warning was "OVERHEATING." The ambient temperature here in the shack is about 24 C, unlike Clipperton where it would have been roasting up into the 40-45 C range!

I have emailed Will at ACOM to see what he says. I'll also copy him on this one. I know amps tend to roll off a bit in terms of output power as one goes up in frequency, but I can get 1,1K or better on HF, so I'd expect 1K on 50-MHz. This may be something that Will or Krassy have seen before.

Paul,

Another data point. 50.120 MHz
38 watts drive
818 watts out
690ma
2400 v
12.1 db gain (same as HF)
Driving it harder results in an "excessive plate current" flashing warning.

I seem to recall having a full 1000 watts out when amp was new to me..

Paul,

I just tested 50Mhz again and on a dummy-load I get 1080 Watts out. Loading and tuning is a bit more critical then on HF. The Plate current is 690mA the. When driving it more I got the "Plate Warning" message. So Ia over 700mA seems not healthy. The RF power gain is also 14dB here and is a bit higher then on HF (between 11,5 - 12dB)

Goodluck and pse post the follow up here on the reflector. I'm curious what the cause is. I'm sure Acom will fix this.

Hans,

I've been using the Acom 1000 with the K3 since Decemeber '07 on CW and have no problems whatsoever. Normally use QSK also and never had any complaints from the amp even after doing the keying mod in the K3 which brings the switching time down to about 8ms.

Just the one keying line is used from KEYOUT on the K3 to KEY IN on the amp, couldn't be simpler.

This is another urban legend, I think. I really doubt if any GU-74b tubes were made very long after the breakup of the Soviet Union. The ones I have came in sealed boxes that had sealed plastic bags inside, and a set of specs written in Cyrillic. These "instructions" had dates written in the format 17.06.87 which I interpreted to mean it was made on 17 June 1987 . . . the "instructions" all had different dates. There is Cyrillic writing on the tubes that doesn't make a lot of sense to me, and nothing except "CCCP" jumps out as being recognisable. There might be a date code on the tube itself, but if it is, I can't de-cypher it.

My point is, given the large glut of GU-74bs in the 1990s, and the (relatively speaking) de-mobilisation of the former Soviet Union's military, why would the former East Bloc factories still be churning out GU-74bs well into the 2000's? I have no hard evidence to support this, but I doubt if many (any?) GU-74bs were made after 1991 or 1992. Given the massive change Russia and the other CIS countries were going through, why would they still be making GU-74bs?

If anyone has a definitive answer to how to interpret date codes on the actual GU-74b tube itself, or knows for sure when production ceased, I'd be very interested to know.

Don't mix up Svetlana 4CX800A and GU-74bs because, while they are electrically compatible, Svetlana made commercial/amateur equivalents of the military GU-74b. The GU-74b was never made for Ham radio amplifiers! :-) It was made for use in Soviet military equipment.

OTK ist the abbreviation for Quality control and 18 indicates
the QC person.

Hello All,

Is the code 89 12 meaning that the tube is produced in Dec 1989 ?
What's is the meaning of "OTK 18" ?

2657. 6M tripping on ACOM-1000 at 700 watts - FIXED

Yahoo group: acom-list (1999 — 2009)
Date: 2008-04-29 00:19:41 UTC
From: Paul M Dunphy
Topic: 2657 Message: 2657

A week or two ago I posted a query to the list asking if anyone had any problems getting full smoke out on 6M with their ACOM-1000. (Mine was tripping out between 600-700 watts and giving a weird ** OVERHEATING ** message.)

Several of the members of the list asked me to post the resolution if I found one. Here it is:

I spoke to ACOM, and they got me to send them a listing of the various menu parameters on 6M as well as several other bands. Everything looked fine. One of their engineers suggested it likely was RF getting into the amp and confusing the microprocessor. I put RF snap on cores on the coax going in and out. Didn't help. I made a coaxial choke in the shack near where it left the amp. Might have helped a little, but it still was tripping at 750-800 watts. Today I another coaxial choke at the feed point of the 6M beam. This had absolutely no effect. However, I was becoming convinced it was RF getting into the amp. I tried disconnecting the ground strap. No difference.

Then I thought of the AC 240 VAC line. Could it be getting in through the house wiring? I put one of those RF snap-on cores on the power line just before it enters the amp. Problem solved! 1012 watts output on 50.125 MHz. Everything works as it should. This was an easy fix (once I figured out where to put the RF core.) RF can always be cured . . . just takes time to figure out how.

2658. ALC on a ACOM 2000

Yahoo group: acom-list (1999 — 2009)
Date: 2008-05-01 20:44:36 UTC
From: Daniel
Topic: 2658 Message: 2658

Hi folks

The ACOM has, so far as I know, an ALC connector and an ALC Regulation on the back. Does this working properly as any ALC on a PA does?

Daniel, HB9DDS

From: Hans Remeeus
Topic: 2658 Message: 2659

Hello Daniel,

Yes it does. However you'll only need the ALC with older transceivers
with tubes in the PA. With modern transceivers Acom does not recommended
to use the ALC-circuit.

When I use my Acom 2000A in combination with the BAND DATA from Yaesu
transceivers I use the KEY IN and KEY OUT.

Hello Hans

"...Yes it does. However you'll only need the ALC with older transceivers with tubes in the PA. With modern transceivers Acom does not recommended to use the ALC-circuit....

1. If you have an ALC it is allways better to use it. Some TRX, especially the newer ones, have power spikes, that means if you set the output power to 10W in the first millisecond the power will go up to 100W and the circuit of the PA is overdriven and shut down!

-->> Use the ALC all the time!

2. When ACON does not recommend this, I think they dont understand the meaning of the ALC!

3. Fot WHAT reason they do NOT recomment it??

Daniel, HB9DDS

PS:

1. I send an email to the swiss company who sell this ACIM stuff. The answer was, we will have a look at (4 weeks ago).

2. I send an email to ACOM in Bulgaria, NO answer!!!

Well.... my comments to your point 2. above is that Acom Bulgaria seems to
have a policy NOT
to answer questions that could possibly disclose a potential weakness in
their products or company
policies......
I am sorry to say that my respect for Acom and their products has gone "down
the drain" over the past
few weeks....
I you wonder what I mean to say please check my earlier postings to this
group...
they did not say anything about ALC however...
***USE the ALC as you should on any transceiver/PA.....BUT adjust it
correctly..and use your
drive level (pwr out) on your TX correctly !
otherwise the dynamic (2-level) bias in the Acom amp will not work properly
!***
I doubt if any ALC will be fast enough to kill the infamous powerspikes
unless you apply a fixed bias
to your ALC-circuit...
This is a general problem and not a specific Acom problem...

I never did true measurements, but don't believe either that the
ALC-circuit is capable of avoiding the powerspikes.

I have such powerspikes with my IC-775DSP and not any with the FT-1000D.
Both I connected to the Acom 2000A.

What Peter wrote is important: when you want to use the ALC, go ahead.
But always adjust the drive and/or power level to protect the linear as
much as possible.

This is what the Technical Reference of the 2000A says about the ALC:

The ALC signal is grid-current derived. When the control grid (G1)
current appears during transmission between zero and 5mA (both tubes
summary), the ALC voltage is zero. When this threshold is exceeded, a
negative voltage appears on the ALC output, which is linearly
proportional to the amount of grid current above the 5mA threshold. Its
maximum value (-11V) is reached around 15mA grid current, and can be
continuously reduced to zero via the ALC regulator. The regulator is
located on the rear panel, just above the ALC connector. Clockwise
rotation will increase the maximum ALC voltage (and the loop gain of the
system "amplifier + transceiver").

Using this output is normally not needed with modern transceivers.

The electrical parameters of the ALC output are as follows:
- maximum output voltage (negative to ground) up to -11V;
- output resistance about 500 Ohms;
- maximum output current up to -10mA (self-protected).

Dear group-members,

This article could be interesting for you:

http://www.nitehawk.com/sm5bsz/dynrange/dubus205/dubus205.htm

Please note the dramatic improvement in the IC-718 and IC-7800 that was
achieved by disabling the ALC.

2665. ACOM 2000A Heater Connector Solution

Yahoo group: acom-list (1999 — 2009)
Date: 2008-05-16 00:16:19 UTC
From: sam_w4pk
Topic: 2665 Message: 2665

Hello all. I finally figured out my heater problem. It was a loose connector (not involved with the heater circuit) on the LV board which I had accidently caused when I originally removed it. I did this the hard way by removing each board one at a time to get at the bottom board. After going through this, it became obvious that there is a much easier way of getting to the bottom board.

I have thus written up a procedure for gaining access to the suspect connectors in case any of you are interested. I found my problem at the tube deck heater connector, not at the LV board connectors. I did not repair the LV connectors as they were okay, but I needed to document how I got to the LV board in case I have a failure in the future. Also included is a procedute for getting at the connector under the tube deck, which turns out to be fairly easy.

PROCEDURE FOLLOWS:

Early ACOM 2000A amplifiers have been reported to have problems with the heater connectors on either the low-voltage (LV) supply board or on the connector underneath the tube deck.

The 13.5VAC heater voltage from the low-voltage transformer is applied to the LV board on a 4-pin Molex connector (JP5), and then is routed via JP6 (another 4-pin Molex connector on the LV board) to underneath the tube deck to another 4-pin connector, JP1.

The LV supply board is at the bottom of the 4-board stack on the front right-hand side of the amplifier when it is viewed from the front.

LV SUPPLY BOARD REMOVAL PROCEDURE:

1. UNPLUG AMPLIFIER, MAKE SURE ALL CAPS ARE DISCHARGED.

2. Unplug all the connectors on the HV power transformer. There are four connectors total, with three of them going to the HV supply board (on top of the stack).

3. Remove the HV transformer, which is in the right-rear of the cabinet when viewed from the front. The transformer is attached via four large Phillips-head screws feeding up underneath the chassis. One way to get at the screws is to turn the amplifier on its side (obviously, with the transformer being down) and removing the four screws. Padding is recommended between the transformer and the bench to ease the stress on the screws and cabinet shelf. Another way is to slide the amplifier over the edge of the work bench far enough to access the four screws underneath the chassis. Be sure to support

the chassis with one hand while you do this as the weight of the transformer will otherwise tip the amplifier off the shelf. Once the transformer is removed, the chassis will be stable to allow the removal of the LV transformer.

4. Remove the 5" brass rod connecting the top board to the chassis. This rod is at the right-rear of the HV rectifier board, and will make the removal of the LV transformer and LV supply board easier.

5. Slide the amplifier off the edge of your work bench far enough to access the six screws holding the LV transformer from underneath the amplifier. Remove these six screws, and lift the transformer to one side to allow the LV transformer secondary connectors to be unplugged from the LV supply board. Once unplugged, place the LV transformer to where the HV transformer was previously located. It will still have its primary cable harness connected.

6. There are six more screws underneath the amplifier which hold the LV Supply mounting plate. Remove these six screws. The LV supply should now be free to remove for easy access. Unplug the remaining cables.

7. If required, either replace the JP5 and JP6 connectors or directly solder them to the LV board. These two connectors are at the right-rear corner of the LV board when viewed from the front of the amp.

8. Once repaired, reverse the procedure above to reinstall the boards. Don't forget the 5" stand-off brass rod for supporting the HV supply board.

Note that the entire 4-board stack can be removed by this process, if desired.

TUBE DECK JP1 REMOVAL PROCEDURE:

1. Turn the amplifier on its side, with the bottom facing to you and with the tube deck at the top.

2. Remove the plate on the bottom of the tube deck.

3. Unplug the air flow sensor connector to allow its cable to be moved to one side. The air flow sensor board is mounted to the plate which you have just removed. Also, the input 50-ohm load is mounted to the bottom plate, and it is still connected via coax. Set the bottom plate on the top of the chassis, taking care to not strain the input coax cable.

4. Unsolder R7, a 47-ohm 2W resistor connected to the rear tube socket, pin 5. The other end of this resistor goes to pin 1 of JP2.

5. JP1 and JP2 are on a small circuit board mounted underneath the tube deck at the extreme rear of the cavity. JP1 is the heater

supply connector (4 pins) and JP2 is a smaller 4-pin connector containing the screen supply source and a heater measurement test point. Remove the smaller plug, and if possible, also remove the heater connector. Remove the two screws holding this board in place. These screws are accessable on the top of the tube deck. It will help if you remove the rear tube and chimney to allow easier access to these two screws.

6. There is enough slack in the wiring harness to allow the board to be pulled out far enough to allow access to the 4-pin JP1 connector. Remove this connector, and solder the wires directly to the board. Make sure that you maintain the correct order for wiring.

7. Reinstall the board, and plug back in the the screen supply connector JP2.

8. Solder the resistor back to the screen of the rear tube socket (pin 5).

9. Plug in the previously removed connector to the air sensor board, and screw the bottom plate back to the underneath of the tube deck.

END OF PROCEDURE.

Again, thanks to Dennis N6KI and Hal N4GG for their suggestions in solving this problem.

73, Sam W4PK

2667. GU-74B heater current

Yahoo group: acom-list (1999 — 2009)
Date: 2008-05-23 00:18:46 UTC
From: hb9tmw
Topic: 2667 Message: 2667

Hi

I recently bought a pair of NOS GU-74B tubes on eBay. I started heating them carefully (PA7TWO provided me some valuable information on testing spares, TNX Kees)and one tube's heater draws 4.2 A at 12.5 V while the other one draws 3.6 A at the same volage.

4.2 is about 8% over the max current specified by the manufacturer (the specs are 3.6 +/- 0.3 A). I wonder if this is meaningless or if the tube is bad. Any ideas?

Hi again

I searched the archives (which should have be done before posting ;-)
and I found some VERY interesting information in post 905. The Acom
2000A will accept heater currents up to 4.4 A, so if Stan at Acom says
4.4 A, 4.2 will just be ok...

Go through post N° 905 there's plenty of good stuff from the Acom
factory in it!!

I know how easy it is to overlook keeping the air filter clean.

You should check it to ensure it's not full of dust!

Our Acom units do not like restricted air flow.

2676. ARC Fault - Low Gain Fault - PROT Fault ACOM 2000A

Yahoo group: acom-list (1999 — 2009)
Date: 2008-06-12 14:44:42 UTC
From: Richard Zalewski
Topic: 2676 Message: 2676

I had been getting all of the subject faults and was getting concerned. I am using a Pro3 to drive the 2000A. I decided to test it with just the Pro driving the ACOM into a 10KW dummy load. I ran some contest software and had it repeat a CQ with a 2 second delay. The error would should itself within 3 minutes.

After discussing this with Will I sent the amp back. Will at the time thought either a tube or maybe relay problem. After extensive testing there they could find nothing so the amp is on its way back to me. Will suggested two things. Either a bad coax drive cable from the Pro to the ACOM or unstable line voltage. It is not the latter. I have a hard time thinking that a coax (RG8) with 30 watts of drive would be the problem but I took the advice and have trashed that coax and replaced it with another after checking it physically for any problems.

Now the question. Has anyone else had similar problems? Solution or suggestions.

Definitely replace the cable. But if that doesn't work, try it with a
different transceiver.

Your Pro3 could be producing a leading-edge spike. Low Gain means the
amp doesn't like the ratio of the input and output power. It's
possible the rig is producing a 150W-200W momentary spike, which can
happen if the internal ALC isn't adjusted correctly or has a faulty
design. I had a TS-950SDX that produced nasty leading-edge spikes
that big, and some ICOM rigs have that problem. The amp probably
wouldn't like a ratio such as 150W/1500W or worse.

My Alpha 87A used to get a low gain fault with the 950. Evidently,
the Alpha firmware checked for the low gain condition before checking
the drive level. Acom firmware is designed differently, so I don't
know if it would produce a low gain fault or an excessive drive fault
in response to a spike. Will might not know, but I'm sure Stan in
Bulgaria does.

Dick makes an EXCELLENT point regarding the leading edge spike. Icom radios are particularly likely to produce this spike. I have experienced it many times with the IC781 in my shack and the way we control it is to adjust the rf power output control to the right level, but more importantly, the DRIVE control must be set properly. As you noted in your report, the problem may not appear immediately. I have seen the condition change over time - perhaps as a result of heat-related factors - so you may have to adjust the levels in response to different circumstances. You should feel good that the amp was certified as working fine when Will tested it.

Hi Dick,

I had something kind of similar with an ACOM-1000. It worked
fine on all HF bands, but if I exceeded 800 watts on 50-MHz, it
tripped out on oddball errors sort of like what you are describing.

It turned out to be RF getting into the amp and "confusing" the
microprocessor. Will was suspicious of this, and I tried a coaxial
choke at the antenna feed point. No luck. Tried putting those RF
cores (snap on chokes) on the coax (both RF in and RF out) at the
amp. No luck. It ended up bring a case of it getting in through the
240 VAC cord. I put an RF snap-on core on the AC line as close to
the amp as possible and this fixed the problem. So . . . look for RF
as well. (I'm driving a 1000 with a PROIII, so it's a similiar
configuration.)

If it does turn out to be a leading spike from the PROIII, you
likely can fix it by adding one of those amp relay buffers.

From: JOEL
Topic: 2682 Message: 2682

ACOM 2000 OWNERS.....As a new owner of an Acom 2000A, I had a similar problem late last year. It appears that my Yaesu FT2000D was producing a "forward spike" that would shut down my Acom 2000 with a fault error. You can see the spike on a scope and sometimes on the small PCU display. There are two ways to get rid of the above problem;

1, If you're running a Yaesu FT-2000(D) or anything that produces a spike, you must cut down on the output of the Yaesu for example to about 50 watts. Not only cut down, but you must also adjust the internal menu number 142 (on the FT2000D) to allow no more than 50 watts.

2, Sometimes the above procedure will not work 100% of the time. However, I decided to use a small PC board made by a company in South America and sold here in the US. The product is called "AMPLIFIER SEQUENCER and made by NETCERTUS (www.netcertus.com) and sells for about $39. Check it out as this is the only thing I came up with.

Hello Joel,

Many thanks for this very interesting and important information about
the amplifier sequencer!

With my Acom 2000A and a few 200 Watt rigs I suffered power spikes too.
Never heard of the sequencer before.

Joel,

Your response is very good. I have not had that problem but do know that a lot of radios DO NOT keep their instantaneous power to the proper level even though they are defined in the menus. The peak drive power can drive the Acom to unbelievable output power and most likely will shut down the Acom amps. I do not have that problem with my Pro3 or Ft847. The sequencer is a great idea and I use them in UHF for mast mounted preamps, there are many out there. With the problem obtaining new finals, great protection idea.

I have thought about a sequencer for the PROIII and 2000A and have
been advised by more than one that it was not necessary. I looked at
the Ameritron ARB704 amoung others. The fault problem here shows up
on cw and ssb.

You should also be able to use the new Heil foot switch which will
key the amp a few milliseconds before the rig is keyed.

It seems that most are missing the problem. Having the amp already in
the xmit mode doesn't solve it- be it via sequencer, foot switch or
whatever.

It is not a hot switching problem. It is a problem with the exciter
putting out 100+ watts of drive at the beginning of the first CW character.
This trips the amp. A scope will show such a spike on many rigs. Beg
or borrow an oscilloscope to confirm the problem if you suspect it.

Somehow one must reduce the amount of the spike to solve the problem.
That may mean relegating some rigs to the trash bin.

A sequencer that perhaps dumps the first few ms of power from the
exciter to a dummy load might work, however, the problem is not one of
sequencing.

Read the specs over carefully for the 20-60 ms is what's needed. When I got my Acom 2000 I went crazy trying to solve the problem. The pc board is the closest I've come where I now do not have the problem.

By any chance is this a problem of the amp being keyed too slowly?
I assume you are using the amp key line from the rig. Is this a relay that is keying the amp? If so, is there a faster signal on the back of the rig that you could use to drive a power mosfet to key the amp? It might turn on the amp quicker which may help the problem of the initial spike of RF? I used to do this with Kenwood rigs. The amp keying relay was too slow. Used "transmit on" to drive a mosfet which turned on the amp.

At one time I had a problem with the Alpha detecting RF before the relays in the amp were closed. The mosfet took care of that issue.

Dear Paul,

Read my past e mails to the reflector for I fully explained everything in detail.

The company in the UK has picked up atleast 100 plus orders for the GU74B and after testing is shipping same now. Look up VINE ANTENNAS (www.vinecom.co.uk) and take a look at their new GU74B tester just finished. Ron has access to purchasing the tube, matching and testing, etc.

I assume you are using the amp key line from the rig. Is this a relay that is keying the amp? If so, is there a faster signal on the back of the rig that you could use to drive a power mosfet to key the amp? It might turn on the amp quicker which may help the problem of the initial spike of RF? I used to do this with Kenwood rigs. The amp keying relay was too slow. Used "transmit on" to drive a mosfet which turned on the amp.

At one time I had a problem with the Alpha detecting RF before the relays in the amp were closed. The mosfet took care of that issue.

I tried the Heil foot switch and that did not do the trick entirely. It did help just a small amount. The amp sequencer got rid of the forward spike problem atleast in my mind. It may not have taken care of the reason for the spike but who cares for I no longer have to think about it until it was just brought up on here. Hey, for a big $39. who cares.

You should also be able to use the new Heil foot switch which will key the amp a few milliseconds before the rig is keyed.

When I got my Acom 2000 I went crazy trying to solve the problem. The
pc board is the closest I've come where I now do not have the problem.

I first came across this problem when I had to borrow an Icom 706 MkI
for a contest when my IC756 was out of action. The 706 was UNUSABLE
with my Acom 1000 on CW because this radio has a major (well known)
fault with its TX power control circuit. When keyed on CW the first
dot or dash starts at full power (100W) then within a couple of
milliseconds drops to the level set by the power control.

I see that the sequencer you have modifies the cw keying waveform to
delay the key down, if it keys the radio with the PTT after keying the
amplifier, then later keys the CW keying line of the radio then I can
see this would help as it would give the power control circuit time to
settle before any drive is applied to the radio PA. The compromise
must either be a slightly truncated first dit or dah - or slightly
delayed CW. I assume this is acceptable.

On phone (if the problem exists on phone) then the sequencer circuit
probably doesn't help, but then on SSB at least the O/P will not jump
straight to max unless you are shouting while keying the mic. Although
I would be concerned about the physical noise of the mic switch itself
especially with the compressor engaged!

The real problem here is with too long a time constant on the power
control feedback circuit on the radio. This long time constant, if
deliberate, is probably to slug an instability in the power control
feedback circuit. I would be unhappy with the workaround this
sequencer gives as short spikes are still possible on SSB at key down
and may still be there on CW. These spikes will be detrimental to the
valve(s) no matter how short they are.

> Thanks for all of the tips. Keep them coming! The amp is due back
> today. I am not using ALC between exciter and amp. This is suggested
> in the manual. Should I consider that?

You can try it, but I don't think it will help.

Leading-edge spikes have a very fast rise time. The internal ALC
circuits of some transceivers don't kick in fast enough to limit the
leading edge spike, hence the problem. Two things have to happen for
the ALC feedback loop between the rig and amp to work: the amp has to
be fast enough to detect the overdrive and assert the negative feedback
voltage, and the rig has to be fast enough to detect and react to the
negative feedback voltage. All this has to happen before the drive
exceeds the amp's tolerance.

You may have other problems if you use ALC. Amp manufacturers generally
discourage use of ALC because it can result in non-linear operation.
The two ALC cicuits really need to be designed together to work
properly.

Rudy at EMTROM from Australia indicated there were no more GU74B tubes for sale with his amplifiers. He also stated that he is changing the tube final(s) to the 4CX1500A tube as per his booth in Dayton.

GU74B(s) are available from Vine Antennas in the UK. Read my old e mails and obtain the infomation necessary. Only NOS tubes are available today.

Tonight I spoke with my friends who were with me at Dayton, to see if they remember more about the conversation we had with the EMTROM guys. The guys in the booth had Russian accents. The tubes they were talking about are the 4CX800□s not the GU74b. They said they are available for $250 each.

Maybe they didn□t know what they were talking about.

The table at the end indicates the problem only occurs on 10m. Is
that correct?

Have you tuned the amp for each of the antennas? The DRIVE and PLATE
lighs might be coming on at 1.9 KW if the amp is not tuned properly.

2706. Re: [acom-list] Re: ACOM 2000A AMPLIFIER FORWARD SPIKE PROBLEM FINAL RESULTS

Yahoo group: acom-list (1999 — 2009)
Date: 2008-06-18 20:30:40 UTC
From: Richard Zalewski
Topic: 2706 Message: 2706

ACOM 2000a troubleshooting

The problems I was experiencing have been resolved. I wish to thank all who contributed their ideas. I would specially like to thank Will at ACOM for his help. As Will stated he just wants a happy customer and I could not be more happy with the service he and the company provided. One more individual who provided a great many suggestions was Adam VA7OJ. He gave me many ideas in how to approach the problem. Finally my friend Jim W7EJ who spent hours with me on Skype as we ran different tests.

The original problem was a Protection ARC Fault or a Protection Low Gain Fault. Both of these appeared to be intertwined. ACOM went through the amplifier and did not find anything after extensive testing. Per Will's suggestion when I received the amplifier back I replaced the RF drive cable from the ICOM Pro III to the amp. As in the past I placed several Type 31 ferrite beads on both the input and the output to the amplifier. Now I also added the ferrite beads to the 240v power cord and the keying line to the amp.

A very important step was to first retune my SteppIR antenna on each band. Then I retuned the amplifier for each band segment. At this point I could not get the amplifier to fail. Nor did I want it to fail!

Now for a couple of tips I picked up:

Want to know how many hours on your Acom 2000A? With the power switch on in the Amplifier but the remote control unit power off hit <Enter>. Read the number of hours on your amp.

Want to reset the amplifier to factory defaults? Perform step above because once you do this the hours get set to 0. Then turn off the power switch at the amp. Hold down the <ESC> on the RCU and turn the main power switch on the amp at the same time.

Date: 2008-07-11 21:36:09 UTC
From: Richard Cariello
Topic: 2708 Message: 2708

Hello to all,
Its been a long time since I installed new tubes in my Acom 2000a. Just picked up some matched set and want to try them out in my amp. I had the procedure printed out but I can't find them.

Anyone have the instructions and willing to email me a copy.

Thanks,
Rich AA2MF

It is on the Files-list of this group:

Tubes_Replacement_Instruction.txt
2000A Tube Replacement Instructions

Uploaded by N1EU.

There is no document called "Technical
Supplement". We however have an instruction about tubes replacement. The adjustment you mention concerns only the idle currents of the tubes. Here is the whole text of the instruction:

****

This step-by-step instruction is about the tubes replacement and idling currents re-adjustment of ACOM2000A power amplifier. Please follow all details closely since the work is difficult, with many details to keep track about, and might be dangerous too. Do not hesitate to contact your local dealer or nearest ACOM's service for any advice or if you don't feel comfortable with repairs!

W A R N I N G HIGH VOLTAGE!
==========
The amplifier works with high voltages up to 3000V which is LETHAL! For your safety pull the amplifier power plug out of the mains wall outlet and WAIT AT LEAST 30minutes EACH TIME BEFORE you remove the cover of the amplifier. Disconnect all cables from the amplifier (grounding last). Do not touch any part inside before ensuring as described below that no residual voltages are present!

1. OLD TUBES REMOVAL

First pull the amplifier power plug out of the mains wall outlet. Wait at least 30 minutes (or more if the amplifier has been just powered up). Be careful - tubes may be VERY HOT!

Remove the top cover by removing all screws except the eight located in the tube exhaust areas. Make sure that no residual DANGEROUS VOLTAGES are present. For the purpose take approximately 1m of WELL INSULATED lead (adequate for 3000V). Bare about 1cm at its both ends. Connect one of the ends FIRST to the GROUND STUD (on the rear panel), and AFTERWARDS, holding it BY THE INSULATION ONLY at a distance of minimum 10cm, touch with its second end consecutively the copper strip of the plate antiparasitic supressors and each tube anode.

In order to remove old tubes, first unscrew a M3x8 screw located between them, which holds both antiparasitic suppressors to the capacitive

divider (a metal plus teflon cylinder between tubes). Keep the screw and washer for the mounting procedure later.

Unclip (one by one) the anode spring clips from both tubes, pressing to bottom with a finger each tube while removing its clip. Now unthread both temperature sensors (which seem like small transistors) out of the red rubber chimneys. Then unthread the red silicon rubber chimneys out of both anode heatsinks, together with the antiparasitic supressors (keep track not to bend temperature sensor leads).

At last, pull both tubes (one by one) out of their sockets using force directed to TOP ONLY since bending may destroy tube sockets.

2. MOUNTING NEW TUBES.

C A U T I O N
==========
Examine new tubes pins before inserting them in sockets. They must be straight and not inclined in respect to the ceramic base, otherwise any bended pin could damage the socket's spring contacts, thus the socket and/or the tube may become unusable

a) Put carefully one by one the new tubes ON the sockets without pressing nor inserting the pins. Keep track about their pins orientation. There is a larger gap between two pins (a pin is vacant) and it must coincide with the corresponding socket's larger gap. Be extremely careful about the tubes screen-grid ring for not to bend any of the socket's spring contacts. If needed, slide the tube carefully up and down while you align them. After that, count them: there must be 16 contacts clearly seen, close-fitting outside each tubes screen ring. This ensures that no one of the spring contacts has been damaged.

b) Align tubes pins so that EACH one would lay exactly in the gap, and at the width center of the socket's spring contacts. Use very small rotation movements during this alignment. Do not lift tubes during this operation in order not to disorder screen grid ring contacts (otherwise repeat the previous step (a).

c) Using a force of NO MORE THAN 50...60N (about 5...6kg or 12...15Lbs.) in VERTICAL DIRECTION ONLY, push carefully each tube (holding its plate heatsink) in order to insert tubes in the sockets. If you meet a greather resistance, do not force anymore and go back to recheck a) and b). Both tubes must fully seat in their sockets.

C A U T I O N
==========
After inserting tubes recheck all 16 contacts of each tubes screen ring.

d) Orient the red silicon rubber chimneys (together with the antiparasitic suppressors inside) so that:
- their small holes could be threaded over the temperature sensors later;
- the center of both antiparasitic suppressors could be screwed to the

plate capacitive divider.

Now thread by small steps in parallel both chimneys over each tube plate heatsink. Keep track not to bend both temperature sensors during this operation. Clip both antiparasitic supressor's spring contacts to each tube plate and orient their center hole to the capacitive divider nut.

Align carefully both rubber chimneys, so that they firmly contact the tube deck: otherwise a part of air flow would be exhausted uselessly. At last, install and tighten the antiparasitic suppressors to the capacitive divider using the saved at step (1) M3x8 screw and lock washer.

e) Insure that after tubes replacement all the wiring is restored to its former condition.

3. IDLING PLATE CURRENT RE-ADJUSTMENT.

After any tube replacement the BIAS voltage needs to be re-adjusted. There is a sub-menu in the SERVICE menu of the amplifier that is foreseen to monitor the idling current of the tubes (the sum for both tubes is displayed).

a) Pull the amplifier power plug out of the mains wall outlet and remove the top cover (it must have been done at step 2). Remove the front panel by removing four screws at the front-bottom edge, and two at the front-top. Put the front panel laying near the left side of the amplifier. Keep track not to fall it down occasionally during next steps. Install the top cover with at least 5 screws on top.

W A R N I N G HIGH VOLTAGE!
==========
Be careful - the mains voltage 220/240VAC will exist permanently on the mains switch (located on the front panel), and will be now accessible - do not touch its contacts! Keep track that nobody could access mains voltage there and do not leave the amplifier without a supervision during next testing period with front panel removed.

Feed mains voltage, turn on the amplifier and let tubes to work about 30 minutes in STANDBY mode.

Use a small size flat tip insulated screwdriver for next adjustments. Find the Interface PCB which is located at the right-hand side of the amplifier. Two trimmer potentiometers RP1 and RP2 (marked "375mA" and "50mA") control the idling (zero-signal) plate current of the tubes for low- and high-signal levels. Both regulators increase the plate current when rotated clockwise.

b) Do not apply any drive during adjustment. Enter the SERVICE sub-menu from the RCU. Using UP and DOWN arrow buttons, select the following screen :

PLATE CURRENT: mA
GRID BIAS : V

The grid bias voltage is monitored for information only. You have to
follow the plate current while adjusting the two trimmers. Note that RP1
will affect both idling levels, while RP2 - only the low level. That is
why the high level is adjusted first, and then the low level (according
to the pocedure described below).

At this point, the procedure is started by pressing the ENT button. Then
the tubes are first controlled to the high-level idling current. It must
be set between 360 and 390mA, typically 370-380mA. If needed, adjust it
via RP1 marked "375mA". You will have about 15 seconds for this
procedure, after which the tubes are cutted off (the current becomes
zero). You could note a 0/10mA flicker on the display, which is normal
during this period since the measuring resolution step is 10mA.

After a 15 seconds pause the tubes are controlled to the low-level
idling current for another 15 seconds. Now the current must be set
between 40 and 60mA, typically 50mA. If needed, adjust it via RP2
marked "50mA".

After this second session, the amplifier automatically leaves the
SERVICE sub-menu, sensing its initial motors positions and retrieving
last tuning. You may re-enter the SERVICE sub-menu several times in
order to have enough time to make adjustments or just to check the
resultant tubes idling currents.

4. REASSEMBLING THE AMPLIFIER

W A R N I N G HIGH VOLTAGE!
==========================
After the adjustment procedure is completed, switch off the amplifier
and pull the amplifier power plug out of the mains wall outlet. Leave
the amplifier in this state for at least 1 hour in order to let the
dangerously high tubes temperature and residual voltages to drop to
safe values.

After 1 hour has expired, remove the top cover of the amplifier. Then
install the front panel. Check whether the HV transformer's mounting
bolts are properly tightened. At last install the top cover again using
all its screws. Align screws thread to the nuts and do not force them
since any captive nut on the chassis might be damaged.

****

Hi all,

I left my station switched on for 2 hours and when came back found ACOM2000A switched off and RCU giving continuos beep. No one LED indicator lights and LCD is dark. No any reaction pressing any button. I suspect there was lighting nearby , and some statics damaged ACOM and my computer 1 hour before IARUHFC.
ACOM2000A works perfect with RCU from another ACOM, but first RCU gives the sane result with another ACOM. Seems problem is in RCU. What can one recomend to do?

Anyone.....what's the latest status on the 4CX800 tubes?

Are they being manufactured?

Easily available?

If available who is the best supplier?

Average Cost now?

73, Jim

From: N2TK
Topic: 2713 Message: 2720

Wasn't there something a while back about pulling out and reseating the CPU in the RCU? I don't remember the details but this was supposed to fix some power on problem.

Subject: [acom-list] Problem with ACOM2000A RCU

Hi all,

I left my station switched on for 2 hours and when came back found ACOM2000A switched off and RCU giving continuos beep. No one LED indicator lights and LCD is dark. No any reaction pressing any button. I suspect there was lighting nearby , and some statics damaged ACOM and my computer 1 hour before IARUHFC.
ACOM2000A works perfect with RCU from another ACOM, but first RCU gives the sane result with another ACOM. Seems problem is in RCU. What can one recomend to do?

Some IC sockets are not "gas tight" allowing contamination and eventually contact failure. I have found treating IC pins with DeoxIT will help avoid contact problems also. >http://store.caig.com/s.nl/it.I/id.32/.f<

From: K0DAN
Topic: 2723 Message: 2723

To expand on another recent post about Vine Antennas in the UK...I obtained a matched pair from Ron, and the tubes arrived promtply, in good shape, and tested out fine in my Acom 2000A. The printed procedure (on list, not provided by Ron) for the tube swap & biasing was very detailed and specific. The actual labor to open the amp and rebias the tubes took maybe 30 minutes but expanded out to 2-3 hours to allow safety factor for the tubes to cool off and HV to bleed off the plate circuit. I would not hesitate to recommend Vine for their prompt communication, fair & ethical business practices, and delivery on their promises. They also offer a warranty. See http://www.vinecom.co.uk/

2724. uh-oh low bias fault on start up -again

Yahoo group: acom-list (1999 — 2009)
Date: 2008-07-20 22:31:07 UTC
From: kamarty456
Topic: 2724 Message: 2724

I reviewed the posts discussing low bias faults, but did not get any answers.
In February of 2007 I had low bias fault alarm and ended up sending the amp to Acom. To their benefit service was fast and turn around time was excellent. I believe it was a FET failure, about $0.50, in parts.

Now as of July 2008 I'm re-experiencing the low bias fault at start up.
I also have seen some other fault messages. I have turned power off unplugged the amp and some other steps to see if this may be self healing.

Sadly no! Shipping the 2000A from Arizona to Acom is getting quite costly, so can anyone out there offer some experience in resolving this challenge?

It's a shame that you can't view the parameters with the amp power on before the warm up time.

Troubleshooting is awkward so I will be calling Acom/Will first thing Monday.

Attention owners of ACOM 1000 and 2000 amplifiers.....

I just received 2 sets of matched tested GU74B tubes from Vine Antennas for my Acom 2000A. Price was fair and most important, the tubes were tested and certified with documention. This appears to be the only way to go before the price on these tubes go way up there shortly. I know of no other way to purchase these GU74B amplifier tubes.

Check on my previous e mails I had posted concerning more details, etc. I understand Ron at Vine antennas in the UK already had received orders close to 100 pieces and shipped most of them. No one else but Vine has a GU74B tester to check out the tubes.

Be advised

A friend and I ordered 3 tubes

2 for a ACOM 2000A and 1 for my ACOM 1000

The matched set for the 2000A worked fine

the single tube for the 1000 was faulty with low output

Vine Antennas in UK immediately shipped out another tube but we never heard back why the
first tube was faulty even though it was tested in his fixture

I think he went back to the drawing board on that one and commented that maybe he needed
a ACOM 1000 to test the single tubes in

So, when you get your tubes, check them ASAP within the warranty period !!!

What my friend and I did is leave the new tubes in the amp and pulled the existing good tubes out and out on shelf as spares since we both had quite a few hours on existing tubes in amp

Dear all,

I've got some for the ones in the need for some spare GU74B tubes. I've made some of the ACOM reflector users very happy in the past :-)

Contact me off-line, e-mail address OK on www.qrz.com

Cheers,

Vy 73, de Kees - pa7two

Mostly all GU74B tubes in the states are all gone. I don't think you want to buy a tube(s) off E-BAY.

Does this mean Acom locally in the states will not support/sell tubes

for their own product, Acom.

Joel is right. In fact, I had a little conversation with the youngest guy at the Alpha stand in the Dayton Hamvention this year about the availability of the GU74Bs in the states. He told me they´re replacing those tubes in all their amps for Eimac´s stuff because the GU74s are almost impossible to find in the US. I would also recommend Ron at Vinecom UK as the most reliable source to buy tubes actually. 73s

My testimonial:

I've bought my spares from Kees, and can attest that everything went smooth. Tubes were OK, and packed with care.

Is Kees getting bashed here?

He's a good guy, honest, and has the hardware & skills to degas NOS tubes.

Maybe I'm reading these threads wrong, maybe the wording is unintentional, but I hope he's not getting beat up, as he doesn't deserve it.

The Acom 1000 series needs only one tube, the Acom 2000 requires a matched pair. Some of us Acom users need one tube, some of us two.

I bought spare tubes from Ron at Vine, mainly because he provides matched, tested, and guaranteed pairs. Had I not needed matched tubes, I might well have purchased
from Kees.

To randomly tosds in a pair of tubes that may or may not have the same operating characteristics is asking for trouble, at least in the form of shortened tube life. You want the pair of tubes to each be doing about the same amount of work, ie drawing about same current, exhausting about same heat.

The rebiasing procedure is well documented, and is a simple two pot adjustment. It takes more time to open and close the amplifier case, and to allow the tubes to cool, than it does to make the actualy adjustment (which is measured on the Remote Control Unit).

The GU74B's are rare enough. And as someone suggested, buying on Ebay carries the highest risk. Let's not bash those who are reputable and honest and can supply these tubes. Both Ron and Kees are among those. There are probably other reputable sources out there as well.

Hello

I have buy 2 spare on ebay look at :
http://cgi.ebay.com/TUBE-GU-74B-GU74B-4CX800-NEW-IN-PLASTIC-BOX_W0QQitemZ300
241756911QQihZ020QQcategoryZ48710QQrdZ1QQssPageNameZWD1VQQcmdZViewItemQQ_trk
sidZp1638Q2em118Q2el1247

No waranty but it was the same for all NOS tube except at VINE.

I don't think anyone is getting bashed. Prior to 2006 there were cheap tubes available in NA. In 2007 the supply dried up. The only place to get them was from European re-sellers and they were NOS GU74b tubes, not 4CX800As. I found a guy in Ukraine who sold me reasonably priced tubes. All four I got worked fine. I don't need any more.

Kees has sold tubes off and on, and by all reports, his prices are reasonable and the quality is as good as anyone else.

Vine Electronics in the UK is the ONLY company anyone seems to be able to find that sells NOS GU74b tubes. Also, Vine tests them and guarantees them. Apparently you pay more for this testing and guarantee. There is nothing wrong with that.

I don't see where anyone is bashing anyone else, or any company. If anyone needs to be asked a question, it's ACOM themselves. Shouldn't the supplier of an amplifier be able to sell all spare parts, including tubes? I love my ACOM-1000, but I feel I should have been able to get a spare tube from ACOM USA, and not have to take my chances on NOS tubes. That's the only "bashing", and it's a minor one.

These are great amps, and all the tube vendors are doing their best to supply a once common tube, now that they have become scarce.

73, Paul VE1DX

I have to agree with you. It doesn't make me the list bit happy that I paid
alot of money for an ACOM 1000 and ACOM can't supply spare/replacement
tubes. It makes me wish I had bought a different amplifier.

This is likely to be a failed antenna switching relay in the output circuit. It can be repaired at home, but requires taking the front panel off to get to the relay on the 2000A. I have replaced my relay within the warrantee period and ACOM was very helpful. I suggest you call ACOM and explain the problem to them.

From: kamarty456
Topic: 2724 Message: 2754

As a follow up to my original posting ....

It has been determined I have a tube failure.
I suspected this, as the amp is almost 8 years old with original tubes.
The run time though is only around 3000 hours. I also never abused the amp.
I suspect the last bias error issue may have effected the longevity of the tube.
I will have both tubes replaced and a new matched pair installed so I can start out as if the amp was new.

I have read tube life as little as 500 hours to an excess of 10,000 hours. I suspect 3000+ hours is closer to a real value for the tube life as we use it.

For those of you with low bias error messages check with Will at Acom to be sure it's not the low voltage or bias circuit instead of a tube. But if you get a low bias error fault frequently I suspect you will be replacing a tube soon.

If I get anymore specific details I'll share it here.

Marty KA7GKN

2757. Installing GU74B tubes in Acom 2000a

Yahoo group: acom-list (1999 — 2009)
Date: 2008-08-02 03:28:45 UTC
From: aa2mf
Topic: 2757 Message: 2757

Hello to all,
I just received two matched sets of GU74B tubes from Vine. At first I thought the tubes were defective, not putting out full power when placed in my Acom 2000a. After doing some research I found the low output to be caused by an incomplete instalation on my part. To prevent others from doing the same I am including what I have found to be the complete process in replaceing the matched set of GU74B tubes in my Acom 2000a.

First of the two stage process. The second stage is very important so don't miss doing it.

FIRST STAGE

ACOM 2000A TUBE REPLACEMENT INSTRUCTIONS

This step-by-step instruction is about the tubes replacement and idling currents re-adjustment of ACOM2000A power amplifier. Please follow all details closely since the work is difficult, with many details to keep track about, and might be dangerous too. Do not hesitate to contact your local dealer or nearest ACOM's service for any advice or if you don't feel comfortable with repairs!

W A R N I N G HIGH VOLTAGE!
==========
The amplifier works with high voltages up to 3000V which is LETHAL! For your safety pull the amplifier power plug out of the mains wall outlet and WAIT AT LEAST 30minutes EACH TIME BEFORE you remove the cover of the amplifier. Disconnect all cables from the amplifier (grounding last). Do not touch any part inside before ensuring as described below that no residual voltages are present!

1. OLD TUBES REMOVAL

First pull the amplifier power plug out of the mains wall outlet. Wait at least 30 minutes (or more if the amplifier has been just powered up). Be careful - tubes may be VERY HOT!

Remove the top cover by removing all screws except the eight located in the tube exhaust areas. Make sure that no residual DANGEROUS VOLTAGES are present. For the purpose take approximately 1m of WELL INSULATED lead (adequate for 3000V). Bare about 1cm at its both ends. Connect one of the ends FIRST to the GROUND STUD (on the rear panel), and AFTERWARDS, holding it BY THE INSULATION ONLY at a distance of minimum 10cm, touch with its second end consecutively the copper strip of the plate antiparasitic suppressors and each tube anode.

In order to remove old tubes, first unscrew a M3x8 screw located between them, which holds both antiparasitic suppressors to the capacitive divider (a metal plus Teflon cylinder between tubes). Keep the screw and washer for the mounting procedure later.

Unclip (one by one) the anode spring clips from both tubes, pressing to bottom with a finger each tube while removing its clip. Now unthread both temperature sensors (which seem like small transistors) out of the red rubber chimneys. Then unthread the red silicon rubber chimneys out of both anode heatsinks, together with the antiparasitic supressors (keep track not to bend temperature sensor leads).

At last, pull both tubes (one by one) out of their sockets using force directed to TOP ONLY since bending may destroy tube sockets.

2. MOUNTING NEW TUBES.

C A U T I O N
==========
Examine new tubes pins before inserting them in sockets. They must be stright and not inclined in respect to the ceramic base, otherwise any bended pin could damage the socket's spring contacts, thus the socket and/or the tube may become unusable

a) Put carefully one by one the new tubes ON the sockets without pressing nor inserting the pins. Keep track about their pins orientation. There is a larger gap between two pins (a pin is vacant) and it must coincide with the corresponding socket's larger gap. Be extremely careful about the tubes screen-grid ring for not to bend any of the socket's spring contacts. If needed, slide the tube carefully up and down while you align them. After that, count them: there must be 16 contacts clearly seen, close-fitting outside each tubes screen ring. This ensures that no one of the spring contacts has been damaged.

b) Align tubes pins so that EACH one would lay exactly in the gap, and at the width center of the socket's spring contacts. Use very small rotation movements during this alignment. Do not lift tubes during this operation in order not to disorder screen grid ring contacts (otherwise repeat the previous step (a).

c) Using a force of NO MORE THAN 50...60N (about 5...6kg or 12...15Lbs.) in VERTICAL DIRECTION ONLY, push carefully each tube (holding its plate heatsink) in order to insert tubes in the sockets. If you meet a greater resistance, do not force anymore and go back to recheck a) and b). Both tubes must fully seat in their sockets.

C A U T I O N
==========
After inserting tubes recheck all 16 contacts of each tubes screen ring.

d) Orient the red silicon rubber chimneys (together with the antiparasitic suppressors inside) so that:
- their small holes could be threaded over the temperature sensors later;
- the center of both antiparasitic suppressors could be screwed to the plate capacitive divider.

Now thread by small steps in parallel both chimneys over each tube plate heatsink. Keep track not to bend both temperature sensors during this operation. Clip both antiparasitic suppressor's spring contacts to each tube plate and orient their center hole to the capacitive divider nut.

Align carefully both rubber chimneys, so that they firmly contact the tube deck: otherwise a part of air flow would be exhausted uselessly. At last, install and tighten the antiparasitic suppressors to the capacitive divider using the saved at step (1) M3x8 screw and lock washer.

e) Insure that after tubes replacement all the wiring is restored to its former condition.

3. IDLING PLATE CURRENT RE-ADJUSTMENT.

After any tube replacement the BIAS voltage needs to be re-adjusted. There is a sub-menu in the SERVICE menu of the amplifier that is foreseen to monitor the idling current of the tubes (the sum for both tubes is displayed).

a) Pull the amplifier power plug out of the mains wall outlet and remove the top cover (it must have been done at step 2). Remove the front panel by removing four screws at the front-bottom edge, and two at the front-top. Put the front panel laying near the left side of the amplifier. Keep track not to fall it down occasionally during next steps. Install the top cover with at least 5 screws on top.

W A R N I N G HIGH VOLTAGE!
==========
Be careful - the mains voltage 220/240VAC will exist permanently on the mains switch (located on the front panel), and will be now accessible - do not touch its contacts! Keep track that nobody could access mains voltage there and do not leave the amplifier without a supervision during next testing period with front panel removed.

Feed mains voltage, turn on the amplifier and let tubes to work about 30 minutes in STANDBY mode.

Use a small size flat tip insulated screwdriver for next adjustments. Find the Interface PCB which is located at the right-hand side of the amplifier. Two trimmer potentiometers RP1 and RP2 (marked "375mA" and "50mA") control the idling (zero-signal) plate current of the tubes for low- and high-signal levels. Both regulators increase the plate current when rotated clockwise.

b) Do not apply any drive during adjustment. Enter the SERVICE sub-menu from the RCU. Using UP and DOWN arrow buttons, select the following screen :

PLATE CURRENT: mA
GRID BIAS : V

The grid bias voltage is monitored for information only. You have to follow the plate current while adjusting the two trimmers. Note that RP1 will affect both idling levels, while RP2 - only the low level. That is why the high level is adjusted first, and then the low level (according to the procedure described below).

At this point, the procedure is started by pressing the ENT button. Then the tubes are first controlled to the high-level idling current. It must be set between 360 and 390mA, typically 370-380mA. If needed, adjust it via RP1 marked "375mA". You will have about 15 seconds for this procedure, after which the tubes are cutted off (the current becomes zero). You could note a 0/10mA flicker on the display, which is normal during this period since the measuring resolution step is 10mA.

After a 15 seconds pause the tubes are controlled to the low-level idling current for another 15 seconds. Now the current must be set between 40 and 60mA, typically 50mA. If needed, adjust it via RP2 marked "50mA".

After this second session, the amplifier automatically leaves the SERVICE sub-menu, sensing its initial motors positions and retrieving last tuning. You may re-enter the SERVICE sub-menu several times in order to have enough time to make adjustments or just to check the resultant tubes idling currents.

4. REASSEMBLING THE AMPLIFIER

W A R N I N G HIGH VOLTAGE!
==========
After the adjustment procedure is completed, switch off the amplifier and pull the amplifier power plug out of the mains wall outlet. Leave the amplifier in this state for at least 1 hour in order to let the dangerously high tubes temperature and residual voltages to drop to safe values.

After 1 hour has expired, remove the top cover of the amplifier. Then install the front panel. Check whether the HV transformer's mounting bolts are properly tightened. At last install the top cover again using all its screws. Align screws thread to the nuts and do not force them since any captive nut on the chassis might be damaged.

by ACOM OOD

ACOM International, Inc
71 West Street
Medfield, MA 02052

Will Angenent, K6ND
K6nd@...

SECOND STAGE

AUTO TUNE PROCESS (in my Manual on Page 16, Section 4-1

The manual states to do an Auto Tune when changing antennas. There is no mention of doing an Auto Tune when replaceing the tubes. This should be done to get Max Output.

After djusting the High and Low bias setting put the amp into operate. Press the ENT botton twice. You will see the screen read APPLY DRIVE 10 TO 20W. Set the desired Band and center band frequency. With the RF output set to ZERO and the radio set for a steady output such as in RTTY press the transmitte botton. Slowly increase the RF output to an indication of center on the sliding scale. The AMP will AUTO TUNE then the screen will chnge to AUTOTUNE COMPLETE PLESE REMOVE DRIVE. Remove the drive power. Th Amp is now set to operate correctly on that band. Try driveing the amp to see what the maxamum output power is. Now repeat the AUTO TUNE for each band. Remember to set the band frequency to the center of area you care to operate.

Full RF output
I hope this information is helpfull.

2758. Re:Installing GU74B tubes in Acom 2000a

Yahoo group: acom-list (1999 — 2009)
Date: 2008-08-02 14:31:13 UTC
From: Hal Kennedy
Topic: 2757 Message: 2758

Having been around these amps a lot - I own two - having repaired several, done lots of tube changes and operated mine and others for 1,000s of hours, the #1 problem I see when these amps are in the hands of others is they are operated out of tune. There is a belief the amps auto-tune on a continuous basis. They don't. They auto-tune when you tell them to.

You need to manually direct them through the auto-tune process every time you change anything. Anytime you change antennas. Anytime you change tubes. Anytime it rains and the ground impedance of that 160 vertical of yours goes from 60 ohms to 30 ohms. Every time you crank the tower half way down, etc. The amp just stores settings and goes back to whatever it has stored. If anything has changed since - it has the wrong settings stored. This applies to every band segment too - not just every band.

The typical tip-off that its time to run auto-tune is if the amp is running hotter than usual for a given output, or if you can't get full output. Or if the SWR has changed. Pushing the amp to full output when it is way out of tune can damage the tubes - just like any other amplifier.

At my contest station, the power-up check list (which takes several hours to run to be fully ready to compete at a serious level) includes commanding an auto-tune on every antenna on every band on every band segment on both amplifiers (that kills 45 minutes all by itself). Its surprising how after a month of inactivity something has changed.

Auto-tune often - your tubes will appreciate it.

Best -
Hal, N4GG

2760. ACOM 2000a Update On Tube Replacement

Yahoo group: acom-list (1999 — 2009)
Date: 2008-08-02 18:22:41 UTC
From: aa2mf
Topic: 2760 Message: 2760

Hello to all,
This is the follow up to my first posting concerning tube replacement in my Acom 2000a amp.

First I must complement Ron from Vine Antennas Ltd who supplied me with the GU74B tubes. His help educating me to the correct procedure in tube replacement indicates the extent he is willing to go to satisfy a customer. Ron, Thank you for all your help.

That being said, the tubes received from Vine Antennas Ltd were received promptly and work perfectly providing full RF output on every band in my Acom 2000a amp.

The problem I was having in installing the tubes and corrected with the help of Ron from Vine Antennas Ltd was caused by not doing an AUTO TUNE procedure on each band with the new tubes installed. This procedure was never included with the instructions I had received from anyone on tube replacement.

****
Summary:
Complete instructions included at end of this message.
PLEASE READ FOR YOUR SAFTEY

3. IDLING PLATE CURRENT RE-ADJUSTMENT.

After any tube replacement the BIAS voltage needs to be re-adjusted. There is a sub-menu in the SERVICE menu of the amplifier that is foreseen to monitor the idling current of the tubes (the sum for both tubes is displayed).

a) Pull the amplifier power plug out of the mains wall outlet and remove the top cover (it must have been done at step 2). Remove the front panel by removing four screws at the front-bottom edge, and two at the front-top. Put the front panel laying near the left side of the amplifier. Keep track not to fall it down occasionally during next steps. Install the top cover with at least 5 screws on top.

W A R N I N G HIGH VOLTAGE!
==========
Be careful - the mains voltage 220/240VAC will exist permanently on the mains switch (located on the front panel), and will be now accessible - do not touch its contacts! Keep track that nobody could access mains voltage there and do not leave the amplifier without a supervision during next testing period with front panel removed.

Feed mains voltage, turn on the amplifier and let tubes to work about 30 minutes in STANDBY mode.

Use a small size flat tip insulated screwdriver for next adjustments. Find the Interface PCB which is located at the right-hand side of the amplifier. Two trimmer potentiometers RP1 and RP2 (marked "375mA" and "50mA") control the idling (zero-signal) plate current of the tubes for low- and high-signal levels. Both regulators increase the plate current when rotated clockwise.

b) Do not apply any drive during adjustment. Enter the SERVICE sub-menu from the RCU. Using UP and DOWN arrow buttons, select the following screen :

PLATE CURRENT: mA
GRID BIAS : V

The grid bias voltage is monitored for information only. You have to follow the plate current while adjusting the two trimmers. Note that RP1 will affect both idling levels, while RP2 - only the low level. That is why the high level is adjusted first, and then the low level (according to the procedure described below).

At this point, the procedure is started by pressing the ENT button. Then the tubes are first controlled to the high-level idling current. It must be set between 360 and 390mA, typically 370-380mA. If needed, adjust it via RP1 marked "375mA". You will have about 15 seconds for this procedure, after which the tubes are cutted off (the current becomes zero). You could note a 0/10mA flicker on the display, which is normal during this period since the measuring resolution step is 10mA.

After a 15 seconds pause the tubes are controlled to the low-level idling current for another 15 seconds. Now the current must be set between 40 and 60mA, typically 50mA. If needed, adjust it via RP2 marked "50mA".

After this second session, the amplifier automatically leaves the SERVICE sub-menu, sensing its initial motors positions and retrieving last tuning. You may re-enter the SERVICE sub-menu several times in order to have enough time to make adjustments or just to check the resultant tubes idling currents.

****
AUTO TUNE procedure on each band (SECTION 4-1 Acom Operation Manual)

To select the AUTO TUNE sub-menu while in the Main menu, press ENT twice:

APPLY 10 TO 20W
DRIVE -----< ----------- >-----

The amplifier will then wait for you to apply between 10 to 20W continuous (CW) signal with the desired frequency. If you leave the

amplifier waiting longer then 40 seconds, then it will automatically revert to the Main menu.

The automatic matching process starts the moment power remains constant within the indicated boundaries. The antenna impedance matching is executed automatically in less then 3 seconds and the following message to the operator appears, while the letter "S" is being sent in CW:

AUTOTUNE COMPLETED PLEASE REMOVE DRIVE

****

COMPLETE TUBE REPLACEMET INSTRUCTIONS

ACOM 2000A TUBE REPLACEMENT INSTRUCTIONS

This step-by-step instruction is about the tubes replacement and idling currents re-adjustment of ACOM2000A power amplifier. Please follow all details closely since the work is difficult, with many details to keep track about, and might be dangerous too. Do not hesitate to contact your local dealer or nearest ACOM's service for any advice or if you don't feel comfortable with repairs!

W A R N I N G HIGH VOLTAGE!
==========
The amplifier works with high voltages up to 3000V which is LETHAL! For your safety pull the amplifier power plug out of the mains wall outlet and WAIT AT LEAST 30minutes EACH TIME BEFORE you remove the cover of the amplifier. Disconnect all cables from the amplifier (grounding last). Do not touch any part inside before ensuring as described below that no residual voltages are present!

1. OLD TUBES REMOVAL

First pull the amplifier power plug out of the mains wall outlet. Wait at least 30 minutes (or more if the amplifier has been just powered up). Be careful - tubes may be VERY HOT!

Remove the top cover by removing all screws except the eight located in the tube exhaust areas. Make sure that no residual DANGEROUS VOLTAGES are present. For the purpose take approximately 1m of WELL INSULATED lead (adequate for 3000V). Bare about 1cm at its both ends. Connect one of the ends FIRST to the GROUND STUD (on the rear panel), and AFTERWARDS, holding it BY THE INSULATION ONLY at a distance of minimum 10cm, touch with its second end consecutively the copper strip of the plate antiparasitic suppressors and each tube anode.

In order to remove old tubes, first unscrew a M3x8 screw located between them, which holds both antiparasitic suppressors to the capacitive divider (a metal plus Teflon cylinder between tubes). Keep the screw and washer for the mounting procedure later.

Unclip (one by one) the anode spring clips from both tubes, pressing to bottom with a finger each tube while removing its clip. Now unthread both temperature sensors (which seem like small transistors) out of the red rubber chimneys. Then unthread the red silicon rubber chimneys out of both anode heatsinks, together with the antiparasitic supressors (keep track not to bend temperature sensor leads).

At last, pull both tubes (one by one) out of their sockets using force directed to TOP ONLY since bending may destroy tube sockets.

2. MOUNTING NEW TUBES.

C A U T I O N
==========
Examine new tubes pins before inserting them in sockets. They must be stright and not inclined in respect to the ceramic base, otherwise any bended pin could damage the socket's spring contacts, thus the socket and/or the tube may become unusable

a) Put carefully one by one the new tubes ON the sockets without pressing nor inserting the pins. Keep track about their pins orientation. There is a larger gap between two pins (a pin is vacant) and it must coincide with the corresponding socket's larger gap. Be extremely careful about the tubes screen-grid ring for not to bend any of the socket's spring contacts. If needed, slide the tube carefully up and down while you align them. After that, count them: there must be 16 contacts clearly seen, close-fitting outside each tubes screen ring. This ensures that no one of the spring contacts has been damaged.

b) Align tubes pins so that EACH one would lay exactly in the gap, and at the width center of the socket's spring contacts. Use very small rotation movements during this alignment. Do not lift tubes during this operation in order not to disorder screen grid ring contacts (otherwise repeat the previous step (a).

c) Using a force of NO MORE THAN 50...60N (about 5...6kg or 12...15Lbs.) in VERTICAL DIRECTION ONLY, push carefully each tube (holding its plate heatsink) in order to insert tubes in the sockets. If you meet a greater resistance, do not force anymore and go back to recheck a) and b). Both tubes must fully seat in their sockets.

C A U T I O N
==========
After inserting tubes recheck all 16 contacts of each tubes screen ring.

d) Orient the red silicon rubber chimneys (together with the antiparasitic suppressors inside) so that:
- their small holes could be threaded over the temperature sensors later;

- the center of both antiparasitic suppressors could be screwed to the plate capacitive divider.

Now thread by small steps in parallel both chimneys over each tube plate heatsink. Keep track not to bend both temperature sensors during this operation. Clip both antiparasitic suppressor's spring contacts to each tube plate and orient their center hole to the capacitive divider nut.

Align carefully both rubber chimneys, so that they firmly contact the tube deck: otherwise a part of air flow would be exhausted uselessly. At last, install and tighten the antiparasitic suppressors to the capacitive divider using the saved at step (1) M3x8 screw and lock washer.

e) Insure that after tubes replacement all the wiring is restored to its former condition.

3. IDLING PLATE CURRENT RE-ADJUSTMENT.

After any tube replacement the BIAS voltage needs to be re-adjusted. There is a sub-menu in the SERVICE menu of the amplifier that is foreseen to monitor the idling current of the tubes (the sum for both tubes is displayed).

a) Pull the amplifier power plug out of the mains wall outlet and remove the top cover (it must have been done at step 2). Remove the front panel by removing four screws at the front-bottom edge, and two at the front-top. Put the front panel laying near the left side of the amplifier. Keep track not to fall it down occasionally during next steps. Install the top cover with at least 5 screws on top.

W A R N I N G HIGH VOLTAGE!
==========
Be careful - the mains voltage 220/240VAC will exist permanently on the mains switch (located on the front panel), and will be now accessible - do not touch its contacts! Keep track that nobody could access mains voltage there and do not leave the amplifier without a supervision during next testing period with front panel removed.

Feed mains voltage, turn on the amplifier and let tubes to work about 30 minutes in STANDBY mode.

Use a small size flat tip insulated screwdriver for next adjustments. Find the Interface PCB which is located at the right-hand side of the amplifier. Two trimmer potentiometers RP1 and RP2 (marked "375mA" and "50mA") control the idling (zero-signal) plate current of the tubes for low- and high-signal levels. Both regulators increase the plate current when rotated clockwise.

b) Do not apply any drive during adjustment. Enter the SERVICE sub-menu from the RCU. Using UP and DOWN arrow buttons, select the following screen :

PLATE CURRENT: mA
GRID BIAS : V

The grid bias voltage is monitored for information only. You have to follow the plate current while adjusting the two trimmers. Note that RP1 will affect both idling levels, while RP2 - only the low level. That is why the high level is adjusted first, and then the low level (according to the procedure described below).

At this point, the procedure is started by pressing the ENT button. Then the tubes are first controlled to the high-level idling current. It must be set between 360 and 390mA, typically 370-380mA. If needed, adjust it via RP1 marked "375mA". You will have about 15 seconds for this procedure, after which the tubes are cutted off (the current becomes zero). You could note a 0/10mA flicker on the display, which is normal during this period since the measuring resolution step is 10mA.

After a 15 seconds pause the tubes are controlled to the low-level idling current for another 15 seconds. Now the current must be set between 40 and 60mA, typically 50mA. If needed, adjust it via RP2 marked "50mA".

After this second session, the amplifier automatically leaves the SERVICE sub-menu, sensing its initial motors positions and retrieving last tuning. You may re-enter the SERVICE sub-menu several times in order to have enough time to make adjustments or just to check the resultant tubes idling currents.

4. REASSEMBLING THE AMPLIFIER

W A R N I N G HIGH VOLTAGE!
==========
After the adjustment procedure is completed, switch off the amplifier and pull the amplifier power plug out of the mains wall outlet. Leave the amplifier in this state for at least 1 hour in order to let the dangerously high tubes temperature and residual voltages to drop to safe values.

After 1 hour has expired, remove the top cover of the amplifier. Then install the front panel. Check whether the HV transformer's mounting bolts are properly tightened. At last install the top cover again using all its screws. Align screws thread to the nuts and do not force them since any captive nut on the chassis might be damaged.

Joel,

Thanks for the answer. I would have expected otherwise, since I recently returned my 2000A to Acom for repair, and did not include the RCU. Perhaps Will and Krassy have some "master key" type of RCU that they use for testing/repair.

I seem to recall somebody telling me a long time ago that if you apply a mis-matched RCU, that the RCU will complain, but that there is a way to get past the complaint.

Thanks again.

Dave

Since that "auto tune" feature of the ACOM 2000a is really the
tuning circuit for the final to "match" even 50 ohms....
I'll bet not. It's not really an antenna tuner.

Now if you have the ACOM antenna Tuner which is available for the 2000A...
I'll bet that has a bypass feature.

I swapped them and although a VERY brief message indicating serial #'s didn't match, the amp worked AOK. I had no problem auto-tuning on any band with my RCU on your 2000A. HOWEVER, after putting your RCU back in, the amplifier still auto-tuned properly, even with the stackmatch connected!! I don't understand this. I only swapped once, but it was also AFTER I partially dismantled your RCU and unplugged the connector on the back and then replugged it. At the present time the 2000A's are both auto-tuning properly. The Antenna Master program is working properly as well, switching the antenna as the radio(s) are tuned (both sides). N1MM, however is still not sending QTC's correctly. I just rejoined the group and will post a query momentarily.

There are no physical or operating problems swapping RCU's.
You will get a warning message, but that can be suppressed.
Here is a note that Acom includes on the technical reference CD
available to Acom owners .
Please note that this procedure will erase all user settings in memory !
You will have to tune all antennas on each segment on all bands after doing this.
As somebody stated in another mail Acom 2000 A must be TOLD to autotune,-
or it will use def settings based on 1:1 match on the operating frequency.
Follow the autotune procedure in the manual and do it on a regular basis !
***
copy://
The "Serial numbers not matching" message appears if the RCU has ever been exchanged between two units. However, this message is only informative and it has no physical consequences.

To find out which are the real numbers, you can first erase the memory. Press and hold the ESC button and then turn ON the main power switch (on the front panel) while still holding the ESC button. The erasing procedure should complete in about 5s.
After that, with the RCU only powered, read the numbers in the HELP sub-menu, immediately after a memory erase, and before powering the main unit for the first time. Both numbers should be equal each other at this moment. This is the genuine RCU serial number.

Principally, the RCU and the main units are produced in pairs, so the numbers should coincide with the serial number of the amplifier as printed on its rear panel.

After a first power ON of the main unit, the serial numbers of the amplifier and its tubes are transferred to the RCU flash memory. Only the RCU serial number is preserved. These numbers will be shown in the HELP sub-menu always after that (until you erase the memory again).

If the RCU and the amplifier have been produced in a pair, their serial numbers should coincide again, also after having turned ON the main unit once or more times.

Although the numbers might differ, the warning message would be suppressed and it should not appear after having erased the memory.

In case anyone is wondering, AntennaMaster is a Windows program I wrote to do automatic antenna switching and tuning in my SO2R contest station. Sig is using a beta copy of it in his M/2 station. I haven't decided whether to make the program generally available.

AntennaMaster gets the rig frequenies from the N1MM, Writelog, or Win-Test contest loggers, or from OmniRig, which is a freeware rig communications/sharing utility used by CW Skimmer. AntennaMaster uses the rig frequency information to optionally switch antennas via one or more Hamation Ethernet Relay Drivers.

AntennaMaster also optionally tunes up to three SteppIR antennas. At my station, the SteppIRs are stacked using a MicroHam micro Stack Max, which allows one antenna to be pulled out of the stack and routed to an alternate radio. AntennaMaster gets the stack configuration from the micro Stack Max and tunes each of the the three SteppIRs to the frequency of the rig to which it's been assigned.

Finally, AntennaMaster can optionally send each rig's frequency and selected antenna to an Acom 2000A attached to that rig. The ACOM will then tune to the appropriate segment/antenna. This is particularly nice when you change bands -- you don't have to send a dit or blow into the mic or lose the first part of your transmission while the 2000A tunes.

AntennaMaster makes it pretty easy to fully retune a 2000A, per N4GG's excellent pre-contest checklist recommendation, particularly of you have multiple antennas per band. You just go to a particular band segment, click on the desired antenna, push ENT twice on the RCU, and put the rig in transmit. Then push the next antenna button, push ENT twice on the RCU, and put the rig in transmit, etc. AntennaMaster save you the trouble of selecting the segment and antenna on the RCU.

I've been thinking about adding an autotune feature to AntennaMaster, where it would cycle through every segment of every band, automatically retuning the 2000A for all antennas for that band. I think that could be done without any user intervention if AntennaMaster is configured to use OmniRig for rig communications (it needs to set the rig frequency and put it in transmit, which it can't do via the loggers.) If OmniRig isn't available, the user would have to set the rig to the correct segment, push transmit and click OK in a dialog box.

If this sounds familiar, a very similar global autotune function is available in a DOS application called ACOM.EXE that ships on the Acom CD (I think they still ship the program.) The program works under stand-alone DOS, but I'm not sure it works in a DOS box under Windows. Modern PCs don't provide a stand-alone copy of DOS anymore. I think there's a public domain DOS look-alike that might work, though. Also, ACOM.EXE only supports COM 1 or COM 2 (the rig has to be on one and the amp on the other.) My system doesn't even have a COM 2. Finally, it only supports the FT-1000MP, FT-990 and FT-900 (though you can set the frequencies and TX/RX manually.)

Acom 2000a Heat sensor transistor replacement

Hello to all,
I am looking to replace the transistors mounted in the air flow of my Acom 2000a tubes. These are the transistors which are used to measure the temperature of the forced air cooling the GU74B tubes.

I am also considering installing transistor sockets onto the PC board where these transistors are currently soldered to. Plugging the transistors into the socket during normal amplifier operation, unplugging the transistors during tube removal.

Would anyone have the generic part number for this transistor?
I will try obtaining some from a parts distributor.

Thanks
Rich AA2MF

The temp sensor is LM335Z .
Precision temp sensor.
available from several sources.
This is not obsololete but in current production
and should be easy to find. Just google LM335Z !

Topic: 2770 Message: 2773

These are no transistors, but temperature sensors.

Since contact resistance may interfere with the measurement, I would not mount them thru connectors. But I?m not a specialist.

Thanks for all who helped me with the Low Bias error in my Acom. It turned out that the tubes were OK, and the C2 Capacitor in the rectifier circuit was bad.

Tony,

I had the very same problem and it turned out to be a shorted cap on
the control board in the amplifier...

I worked with Stan at Acom to find the problem. Good Luck.

2783. Fixed my 2000A Low Bias error!

Yahoo group: acom-list (1999 — 2009)
Date: 2008-08-14 23:33:59 UTC
From: Barry
Topic: 2783 Message: 2783

Wasn't a bad tube, after all.

Got some excellent tech support from Stan at Acom, via Tony, N2TK, who kindly provided me with his correspondence with Stan from 2 years ago for the same problem (Acom is on vacation this week.)

Turned out the problem was a bad filter capacitor (C2) on the Low Voltage board. Of course, the LV board is the bottom one in the stack of 3 boards, so the whole thing had to be disassembled, spacer by spacer, bridging ground wires, etc.. It been a while since I tackled a project like this, and fortunately, I had no left over (or missing) parts and no edge connectors that I couldn't figure out where to plug back in :.)

2785. Update Acom 2000a Heat Sensor Transistor Replacement

Yahoo group: acom-list (1999 — 2009)
Date: 2008-08-22 19:24:50 UTC
From: Richard Cariello
Topic: 2785 Message: 2785

Hello to all,
Around the beginning of August I requested information on replacing the Heat Sensor Transistor in my Acom 2000a. This is the follow-up message on the project.

My plan was to replace the Heat Sensor Transistors and mounting them into Transistor sockets. The reason for doing this was do to the bending of the Heat Sensor Leads causing them to break when replacing the final tubes. The additional soldering repairs was starting to cause damage to the mounting circuit board tracings. Normally I would think tube replacement should not need to be done for long periods of time. In my case replacement was done many time while testing newly received tubes causing damage to the Heat Sensor leads and ware on the circuit board traces.

The parts were obtained from Mouser Electronics (www.mouser.com) 800-346-6873. A special thanks to LA7SL Nils "Peter" for sending this information to me.

Precision Temperature Sensors, Part Number 511-LM335Z Mfg PN:LM335Z @ $0.62 each.
TO-5 Transistor Socket, Part Number 534-4590 Mfg PN:4590 @ $1.09 each.

The old Temperature Sensors were removed and the circuit board was desouldered. I found the spaceing of the transistor sockets and circuit board not to match. To solve this I removed the pins from the plastic holder. I then inserted each individual pin into the circuit board and resouldered. I then inserted the leads of the new Heat Sensor Transistor into the mounting pins making sure placement was correct and the leads did not touch each other.

The amp has been running now for a good four hours with some transmit time. All seems to be working as it should be.

I want to thank Stan of Acom and K2QMF for their help solving the problem. It turned out to be C14 in the RCU. It seems there may be a batch of blue colored 22nF caps that show low resistance after a while. C23 is also showing low resistance and will be replaced as soon as I get more caps.

Amp is working fine again.

Topic: 2785 Message: 2789

I've had my tubes in & out about a half dozen times (Acom 2000), one time being a tube swap.

Never had a problem with the heat sensors getting whacked. You do have to treat them tenderly, but this is mostly just guiding them in & out of the chimney material...not very difficult or trickey.

Perhaps dozens or hundreds of tube removals would be more brutal.

A pair of sockets would be convenient for this operation, but then introduces the chance of inverting the compnents when replacing them, also of poorer electrical contact with the leads.

I'd suggest you just go and swap the tubes and treat the sensors kindly. If you do happen to break the leads, you can always add the socket, but "if it ain't broke, don't fix it."

Bill,
In my experience the first time with one lead breaking. Being careful is important but just a simple push and the Heat Sensor leads are bent. Once it happens the leads are now weak and tend to bend then break. Resolder the heat sensor leads then the traces on the circuit board start to go. One repair leads into another. I decided to install sockets with new Heat Sensors starting fresh before I needed to replace both circuit boards. I personally feel more comfortable dealing with socket contact resistance then a pin head of solder holding the leads of the Heat Sensor together. Also from what I have seen the circuit board is not going to handle more then a few Heat Sensor changes or repairs before it becomes unusable.

Don't get me wrong. I'm not advocating installing sockets just for sake of something to do but if your Heat Sensors do get damaged I feel installing sockets as part of the repair is the way to go.

One final point. I could not find Transistor Sockets with the same spaceing of the circuit board. I had to remove the pins from the socket and install each one individually. Not difficult but just another step in the repair process.

Rich,

since now i have my spares , and was going to put the spares & saving
the originals.... I want to ask,.. did the sensor leads go due to
many tube swaps ???or just one "cycle" of assembly/disassembly? I
would like to verify I do have a good set of spares.

tnx

bill

Around the beginning of August I requested information on replacing
the Heat Sensor Transistor in my Acom 2000a.

I wonder if anyone knows the maximum temperature I should run the 2000A? I know there seems to be no ill effects at running it at 65-80C degrees. How about you digital guys- how much power out do you run and how high a temp you get on the tube readouts?

By the way, I had purchased some GU74B's from eBay a while back. I ran them under filament voltage only for 24 hours. Then tried them on the 2000a. Got some to match within 2 degrees at 65C degrees. Guess that is pretty good.

Hello Tony,

Even during 24 hours contests with "legal limit" no problems at all with extended heat!

The shack is very warm and no central heating is necessary, but the Acom 2000A does'nt give a signal that the heat is too much.

Temperature between 65 and 85 degrees C.

I've never had my 2000A complain about heat. I believe those heat sensors in the chimneys not only measure, but will report a fault (shut down amp) in the event of excessive heat. But I'bve never had that happen.

Acom says you don't even need the AUX fan unless you're running 100% duty cycle (eg RTTY) for extended periods. In that case, the AUX fan is probably a wise decision, but I still think the amp will protect itself.

If your tubes run within a few degress of each other, you're doing great! If they start to drift apart, you know one tube is getting tired.

Even if you do start to see a temp difference between tubes, a slight decrease in power out (1KW vs 1.5KW) will not be heard on the air, yet will be more forgiving to an old tube which is on its last legs.

Tnx Dan for that info. I do have the auxiliary fan. It runs all the time. I have a filter on it. Used to check the amp twice a year for dust in the tube fins. But have not had any so far with 7k hours on the amp. So only take the amp down off the shelf in the basement once a year now. Replace the filter every year. Could not measure a difference in tube temp with and without the additional filter.

Been limiting my power out on RTTY to about 350W. Will try cranking it up and see how it goes.

I now have one pair (in the amp) that stays within 2 degrees. One pair that stays within 4 degrees and one pair that stays within 6 degrees. Guess I should be good for quite a while :-)
I had a tube failure a while back with only 6100 hours on the tubes. Thought that was quite low for these type of tubes.

CU in the RTTY pileups with some more power now.

The blower on the ACOM 1000 will speed up when the temperature exceeds 90C, so I guess ACOM thinks the exhaust temperature should stay at 90C or below.

That said, it is not so easy to reach that temperature without continous key-down.

Hello All,

I have a Acom 2000A that is operating strange. The driver is a Elecraft K3. In SSB the K3 set for 40 watts output. The output from the Acom tends to 'jump'. On softer parts of speech the output is a few hundred watts then 'jumps' to 700 or 800 watts. In cw mode the power output is fairly linear over the complete range. Any idea on whats going on here ? I have tried the amp with two K3s and both have the same behavior.
Any ideas welcome !

. Put the power meter in the drive line between K3 and amp.
Check K3's output directly with amp in stby - then with amp
in opr. Could be the K3 does not like strong RF-fields in SSB
mode. Have seen this problem many times with K2 and K3.
I suspect the K's are extremely good receivers with a rather
poor TX " add-on " :-) Have me excused here Elecraft fans...
the receivers really are superb,- maybe not so with the transmitter
part of the Elecrafts...

2806. low gain fault solved ?

Yahoo group: acom-list (1999 — 2009)
Date: 2008-10-19 10:47:48 UTC
From: LA7SL Nils "Peter"
Topic: 2806 Message: 2806

Hi all !
For a long time I have tried to solve a strange problem in
our Acom 2000A . Very often it would protect showing
"low gain fault" . Very often this would be happening :
carrier on from tx. 10 sek normal operation, then power
falls back to abt 600 watts for 1 to 2 sek before protect.
"everything" was tried..including checking tubes.
Then I read a posting here advising ferrite on cables to amp.
This has now been tested extensively. The result is that ferrite
on the RCU cable near the amp helps a lot. Keying line may help.
The problem was intermittent before the ferrites were tried, and more
or less band independent. This made it difficult to evaluate results.
Could be that the decoupling capacitors in the Acom (back panel)
is of insufficient value or quality. The results so far shows that
the low gain fault problems are reduced with a factor ten WITH the
ferrites as opposed to WITHOUT ferrites. Next step will be to change
all back panel decoupling caps and components while keeping compliance
with electrical codes (mains line !) and keying and data line characteristics.
Be careful to chose correct ferrite material !
More later....
Peter

> whats going on here ?

If you haven't already done so, download and install the latest K3 firmware. Later versions result in much more consistent ssb output levels.

Make sure you are using sufficient mic gain. With compression off, a constant "ahhh" into the mic should result in a constant 5 bars on the ALC meter. With my HC5 mic element, I have mic = 30 with the hi gain (mic sel = rP.H) input setting. Finally in the Config menu, set TXG VCE = 1.5 or 2.0dB.

I am ready to pull the trigger to bu my next amplifier. I am impressed with the feedback on the Acom 1000 but my BIG concern is the future availability of the 4CX800A. I want around 800W with 1.8 - 54 MHz coverage. I am also considering th Tokyo Hy-Power 1.5Kfx and even though it has very good reviews I think the ACOM 1000 has more room. I will appreciate any suggestion or explanation on the amp and the 4CX800A issue.

No problem with availability of spare GU74B tubes. Prices go up each year, sure, but no problems to obtain them. Ask me for details if you need spares.
Acom 1000 is a perfect amplifier. See my reviews on both the Acom 1000 and Acom 1010 on www . eham.net.

Best piece of Ham radio equipment I ever purchased. GU74b
(a/k/a 4CX800As) are the only concern, and there are enough NOS ones
available in the $200-$400 range to stock up on 2-3 and have a
lifetime supply. I highly recommend it. Been going almost 12 hours
a day for 1.5 years here, 160M through 6M usage.

Pick up a couple of spares and you will be set for life... They are readily available from many sources but keep on getting more expensive (as is everything else).
Many reputable sources in europe sell them. Jim K4JAF

As stated many times, Vine Antennas in the UK has supplied GU74B tubes AFTER BEING TESTED with a guaranty. Vine has supplied over 125 tubes in the USA and I myself have purchased two sets of these. Yes, they're people in Europe selling these but they are NOT fully tested with a test jig and without specs given out. Check on the VINE ANTENNAS site for a fair price and load up for the GU74B will be going up and up and up in price. I looked around for a wehile but other people have purchased the tubes off E Bay and are NOT in the tube or amplifier business.

Don't worry. This GU74b tube is very solid and will last many many years! Under normal operating conditions perhaps ten years. I paid between 35 untill 60 euro for new GU74b's on several European hamradio markets.

The Acom 1000 is a very solid, reliable and silent linear amplifier. You will like it very much!

2814. tr4b error

Yahoo group: acom-list (1999 — 2009)
Date: 2008-10-20 17:32:40 UTC
From: pa5cw
Topic: 2814 Message: 2814

After one year of cw operation, I ngot a tr4b error.

According to Ron (vine), it could be to low main voltage supply.

After changing the tap on the main transformer, the problem was not solved. There where some other test from Acom, but it was difficult to check it because all of the automatic safety check performed by the cpu in the Acom.

I suspected the output relais, but could not test it, because of the safety checks.

Finnaly I returned the Acon to Ron and it was repaired withouth costs!

The problem was indeed the output relais, so I wonder if the lifetime is limited by heavely use of CW (semi brak in with K3).

What is a TR4B error.....???
And how did you get it.....???
I get a Hot Switching error on my 1000, but when i spoke to Ron at vine, his say's it must be my fault, as load's of people use these radio's with the acom and never get a problem.
So is a TR4B the same as hot switching.....???

Hi Chris,

I had this TR4B just a couple of days ago. See the ACOM1000 manual, chapter 6.5 for an explanation. Apparently the 1000s software periodically checks several parameters when transmitting. I read the TR4B meaning as the checked parameter/signal indicated an open output relay while transmitting. In my case the protection circuitry did an immediate shut-down of the amp - the red light came on. After a while I turned the amp on again and used it in last weekends RTTY contest without any faults.

2818. Heater light flicking on ACOM 2000

Yahoo group: acom-list (1999 — 2009)
Date: 2008-10-21 13:24:34 UTC
From: Callum M0MCX
Topic: 2818 Message: 2818

I know if the heater light flashes, it's because the voltage is too high. Do I take it that if it stays on for any amount of time (a second or two) it means the voltage is too low - or is it something else. Maybe I didn't look in the manual too hard but I use my 2000 mostly for field events and I often get strange voltages to play with.

Hello Callum,

That is correct:

Flashing means that the heater voltage is too high.
Slowly on and off means that the heater voltage is too low.

You can set the range of your voltage in the menu!

Don't worry about the flashing and don't try to change taps unless it becomes consistent. Most power companies will only control line voltage to 5 or 10%, and depending on changing loads you can see some high fluctuations. The problem is usually worse in the spring of fall when air conditioning loads are changing.

Right.

Better for the tubes is a bit higher heater voltage than too low!!

2830. Relay Sticking

Yahoo group: acom-list (1999 — 2009)
Date: 2008-10-31 18:06:40 UTC
From: Dave Hawes
Topic: 2830 Message: 2830

Hello, Group.

I have just diagnosed a problem with my 2000A with regards to relay sticking.

The symptom was that there was an open circuit through the amplifier when it was turned off. Obviously, there should be a closed circuit. There are two relays in the RF path:

NAIS TQ2-12V in the Phase Detector
Kilovac HC-1 in the output

I turned on the amplifier, put the radio in QSK mode and sent dots for about 15 seconds, and the RX sprang to life. Obviously, one of the two relays had stuck in the "Transmit" position.

Here's the question: Which of these is the likely candidate? I know there has been a lot of discussion in the past about replacement of the HC-1, etc, and in fact, I have replaced the relay in this amplifier twice already. I am not opposed to doing it again, but is there any chance that the problem was the input relay, the NAIS DPDT relay?

I have a spare HC-1 in the drawer and can readily replace the installed one, but should I also order up a TQ2-12V "for the drawer" just in case?

2834. One more question -Acom 1000 -

Yahoo group: acom-list (1999 — 2009)
Date: 2008-11-08 16:08:25 UTC
From: coa132435
Topic: 2834 Message: 2834

Any comments in the SWR between the Acom-1000 and the transceiver? Is it below 1:1.5 across all the bands and specifically in the WARC bands of 12m and 17m. Will I need a ant tuner between the radio and the acom 1000?

Thanks in advance

No amp should require a tuner between it and the radio, and the ACOM-1000 shows 50 ohms on all bands when engaged, and is a direct path to whatever the antenna system is when in standby. This includes all bands from 160 to 6. In other words, it will not change your SWR on any band.

Paul,

I have an Acom-1000 and Icom 756Pro. I do not need to tune between them and see no reason why you should.

I don't, Irwin. It was the original poster who asked the
question, not me. When in standby, the amp is invisible and your
radio will see the antenna system(s) as if it were not there. When
in "Operate" all modern amps, including the ACOM-1000, should present
a 50-ohm impedance to the rig. (Some older or less expensive amps
have slugs for tweaking the inputs on various bands, but the
ACOM-1000 does not because it isn't needed.)

If any amp shows a high SWR on any band, something is wrong. I don't know what prompted the original question, as I haven't heard of this being an issue with any model of ACOM amp.

The reason I asked is because this is the first amp I am planning to buy after several weeks of research. Also, some big names in th US advertise that if the amp is used in warc (17 and 12) a tuner maybe required between the amp and the radio (when the amp is switched to operate).

I just want to set my expectations to see what I am expecting after dropping $$$$ for an amplifier.

Thanks for the info.

Set your expectations high with the Acom, no tuner needed or recommended, including WARC. In fact if your exciter has a built-in tuner, it should be disabled when you use the amplfiier!

You will love the 1000. The input swr is pretty much flat on all bands as your driving the input of the tube in parallel with a 50 ohm resistor. Thus no tuned input such as on the 500Z type amps... The acom 1000 is the best amp I have ever used all things considered. Enjoy... Jim K4JAF

I'll even go further than that. (And this will cause some
controversy!) I believe the ACOM-1000 to be a better amp than the
ACOM-2000. Why?

(1) Half the price.

(2) 1000 watts (it will actually put out 1100 or 1200 if you push it)
is all you ever need need. The extra power of the ACOM-2000 is not
worth paying twice as much. Do the basic math about how much gain
you get by doubling the power.

(3) The ACOM-2000 is extremely complicated because it is an auto-tune
tube amp. I have never used one, but all the complaints about odd
error messages seem to come from the 2000. Remember, the odds of
failure is directly proportional to the complexity of any device.

(4) With a 20000, you need to find matched tubes - can't (or at least
shouldn't) replace one or things may go wonky.

(5) I can tune my ACOM-1000 in 5 seconds or less (this comes with
practice, but it can easily be done.) The ACOM-2000's claim that is
can tune on one "dit" at 40 WPM may be true, but who needs
this? Yes, once in 5 years you might get a call or two in before the
hordes show up, but generally speaking the average DXer doesn't need
it . . . maybe it gives the mega-contest stations an advantage.

I use my ACOM-1000 *every day* for 7-8 hours, sometimes it goes
a full weekend during contests. After 2 years of daily use, it still
behaves like the day I got it. Same amount of power out of the
original tube. I do not believe there is an amp on the market that
will give you the dollar per watt value of an ACOM-1000. As I said,
I never had an ACOM-2000, but I have had several other amps over my
22+ year DXing career made by well known and respected
manufacturers. The ACOM-1000 is the best I've ever used or seen.

Great amp. Mine will be 6 years old in month. Used extensively, including in RTTY contesting. Used on all bands. Fabulous amp. No tuner between trnscvr and amp.

I second all those comments and add that the protection circuits on Acom amps often find external faults in exciters, feeders, and aerials before their operators are even aware of them. Several times here I have seen fault codes being resolved by necessary aerial system repairs.

The 2000A seems an excellent amp with a fantastic reputation yet the 1000 seems to beat it easily for reliability.

I second all those comments and add that the protection circuits on
Acom amps often find external faults in exciters, feeders, and aerials
before their operators are even aware of them. Several times here I
have seen fault codes being resolved by necessary aerial system repairs.

The 2000A seems an excellent amp with a fantastic reputation yet the
1000 seems to beat it easily for reliability.

The GU74b is a tetrode and has a higher gain, than the triodes used in some older amplifiers. Therefore you are more or less looking directly into a 50 ohms / 100 W resistor on the input.

The circuit can be seen here:
http://www.xs4all.nl/~wesselva/acom_input.png

2846. Acom 2000A BIAS TOO LOW

Yahoo group: acom-list (1999 — 2009)
Date: 2008-11-11 19:48:48 UTC
From: Glenn O'Donnell, K3PP
Topic: 2846 Message: 2846

Hi gang,

I have one of the first 2000A units sold here in the US and it's now dead with this error. Actually, it's been dead for well over a year, but I've been too busy to deal with it. Now that contest season is under way, I want to get things going again. Better late than never! :-(

I know this has come up here before and my perusal of the list archive tells me my most likely cause is a fried screen or control grid in one of the tubes. Hal, N4GG gave a nice, thorough description here:
http://groups.yahoo.com/group/acom-list/message/2564

Tony, N2TK mentioned capacitor C2 as a culprit:
http://groups.yahoo.com/group/acom-list/message/1693
but then also confirmed the bad tube fault:
http://groups.yahoo.com/group/acom-list/message/2238
Tony, I love ya man, but what's the scoop?

My problem first appeared intermittently, but rapidly turned permanent. I buy Hal's theory because I had a lot of trouble in its early days with spikes from my Icom IC775 kicking it off with arc faults. I finally got that under control, but I suppose the damage was already done.

My two questions:
1. Can I test this to tell for sure?
2. Should I not even bother and just order two GU74B tubes now? If so, it appears Vine in the UK is the best source, right?

I've exchanged email a few times with Will K6ND at Acom. He was helpful, but suggested I send it back to them for repair. I know they're good, and reasonable, but I can't respect myself as a technical guy if I don't at least take a stab at repairing it myself first!

Thanks a 1.0E+06 to all!

Hi Glen --

My Acom 2000A (also an early unit... the first one manufactured
without the fan mount) just had this problem show up a couple of weeks
ago. It was detected during the power-up sequence. As I live near Acom
USA I just took the amp over to the shop. It was a bad tube.

Hi Eric,

Thank you for the response! That's what I suspect too. I sent a message to Vine in the UK to get pricing on two replacement tubes. Even if that's not the problem, it will be good to have the spares on hand. I'm about 5 hours away from Acom, but if I goof this up, I will also drive it to Acom rather than ship it.

I'll keep everyone posted.

Glenn,
I had the problem, too. Turned out to be a bad C2 on the LV board (the bottom one in the stack) and seems to be a not uncommon problem. I got excellent step by step instructions from Stan on how to troubleshoot it and pinpoint the problem. Email Stan, or maybe someone on the list has already emailed you the info.

Well fellow ACOM users:

This is the fall/winter reminder to check your air filters and ensure
they are clean!

A clean filter makes for a happy amplifier

Lesson learned - be careful how you undo the screws on the Acom -1000 filter. The nuts and lock washers are on the inside and I had a tough time putting them back on. A ham friend helped me and we used surgical Kelly clamps to hold the nuts in place while screwing the screen cover back on. I was not able to put the lock washer back on. It would have been better if Acom had used self tapping screws into the chasis. Next time I will just take off the cover and use a vacuum cleaner hose to clean both sides of the filter.

Someone please clear this up for me.

I Have heard a Rumor that the GU74's may be back in production but can't get any solid confirmation.

I have noticed Amps for sell on swap boards or even at dealers tend to sit longer before being sold & usually reduced in price prior to sale.....maybe the tube shortage or whatever you want to call it is the reason.

I guess my question is, "Would you be leery about buying a used 2000A considering the tubes may not currently be in production?

2854. RE: [acom-list] Old Tube tpic

GU74B (A2000A) tubes are being sold by Ron at VINE ANTENNAS in the UK. More than 100 people including myself have purchased the tubes. Look at my previous postings and read all about them as these tubes were not just taken from EBAY. In any event, if you do not push the tubes you'll get 6-8,000 hours easily.

And no, the GU74B tubes are not yet back in production. When they are back to purchase, the price will be 5 fold of what's being sold now as NOS.

Joel, K2QBV

The answer to the question above is I would not hesitate to buy a used ACOM given it was not obviously abused, and the current power output was reasonable, indicating the tubes are working. See Joel's comments of tube availability from Vine in the UK. I also have a pair of those tested and documented spares.

I do not think the tubes are in production,-or will ever be again...
Commercial demand for those tubes is just too low to set up a
production line,- unless somebody is willing to pay thousands per tube (USD)
I also have a strong "feeling" that patent issues or other business complications
may exist. ... I say may exist...I have no evidence !
But I would still not hesitate buying another used Acom. I have had some serious issues
with ours..but they now seem to be solved. (low gain fault/protect) RF environment
is a key word there, as well as periodic (!) tube failure.
Do not trust all sellers claiming NOS tubes, however. They are more or less used all of
them :-) But availability is still reasonably good. I got 4 tubes from PA-land, and 2 of
them
matched to within 2 degrees Celsius at 1.5 KW out. That is good !
Just hurry ! Nobody knows how long they will be around, or at what price...
Never buy an Acom unless you have 2 pairs of matched tubes in house....
I am very critical of Acom still producing these amps ,- knowing they are actually out
of date the day they are sold !! But buying a good used one with 2 (TWO) sets of spares ?
YES ! ABSOLUTELY !

To kill some statements that are somewhat lossy: New GU74B (labled these days as '4cx800a') are still in production at Svetlana factory, also this present year. I asked specifically this question to one of my Russian friends who actually phoned the factory for info after reading rumours earlier this year. I also know the current production price and yes that one is higher as the current prices payed for NOS tubes.

The GU74B tubes are not sold outside the Russian military market since a few years now. I was told that production can be re-started, it is just a matter of who needs many (MANY) of them in one lot. Spare tubes are still available and reasonable prices for at least the next year. Yes, sure, the price will increase, but that is as like all other goods we buy these days. I still have some spare GU74B, GU43B and GI7B tubes and sockets available if one needs in various types: or newly boxed, newly in original and sealed factory plastic bags or just in foil. All are un-used and NOS meaning 'New Old Stock'. NOS to me does not mean "used" or whatever, just 'new' but on the shelf for some years already.
Contact me for details if you need some NOS tubes. Ask the reflectors for feedback if any doubts. Vy 73, de Kees. Director of 'TWOwireZ', antennae and RF tubes.Member of an all HAM family.AmateurRadio : PA7TWO - M5TWO Locator: JO22jp.

Let us PLEASE stop the rumors!!

I just ordered a pair of NOS tubes from Vine Antennas in the UK. Ron at Vine is a reputable guy who has helped many on this list! GU74b tubes are available! Go to the Vine web site to learn the truth:
www.vinecom.co.uk

I hope to install the tubes and be back to full power in time for CQWW CW. I will keep everyone informed.

Hello Kees !
Nobody attacked You !!
Unless you happen to have a bunch of shares in the Acom factory,-of course :-)
We actually got our spare tubes from you ! And,- as I said two of them matched
to within 2 degr. C. and that is VERY good ! (we bought them as unmatched)
So no complaints over you Kees ! I am a satisfied customer :-) ...
And, by the way, you are packing these things to survive a nuclear war ! And that is
excellent,- knowing our postal services here.....
But for the current production situation : I also have my info directly from Svetlana
in St. Petersburg..... They are currently not producing any GU74B or 4CX800a ,-
according to an email they sent to my personal mailbox. That mail arrived early this
summer, so chances are,-of course, that we could both have correct information at
different points in time....they may have started up again.
Another possibility is that they give different info to different people...a situation
somewhat familiar to those who have some business with Russia.. ..
different cultures you know... :-)
But, as I said,-the tubes we got from you are good,- so everything is OK :-)
Peter

Subject: RE: [acom-list] Old Tube tpic

To kill some statements that are somewhat lossy: New GU74B (labled these days as '4cx800a')
are still in production at Svetlana factory, also this present year. I asked specifically
this question to one of my Russian friends who actually phoned the factory for info after
reading rumours earlier this year. I also know the current production price and yes that
one is higher as the current prices payed for NOS tubes.

The GU74B tubes are not sold outside the Russian military market since a few years now. I
was told that production can be re-started, it is just a matter of who needs many (MANY) of
them in one lot. Spare tubes are still available and reasonable prices for at least the
next year. Yes, sure, the price will increase, but that is as like all other goods we buy
these days. I still have some spare GU74B, GU43B and GI7B tubes and sockets available if
one needs in various types: or newly boxed, newly in original and sealed factory plastic
bags or just in foil. All are un-used and NOS meaning 'New Old Stock'. NOS to me does not
mean "used" or whatever, just 'new' but on the shelf for some years already.
Contact me for details if you need some NOS tubes. Ask the reflectors for feedback if any
doubts. Vy 73, de Kees. Director of 'TWOwireZ', antennae and RF tubes.Member of an all HAM
family.AmateurRadio : PA7TWO - M5TWO Locator: JO22jp.

Rumors ???
The question was "are the GU74B's in current production"
and that is the subject for this discussion.
We KNOW that NOS is available --meaning New Old Stock-
please note "old stock" --meaning they are produced some time
ago. And i said "do not trust ALL sellers"
please read before you comment :-(

Let us PLEASE stop the rumors!!

I just ordered a pair of NOS tubes from Vine Antennas in the UK. Ron at Vine is a reputable guy who has helped many on this list! GU74b tubes are available! Go to the Vine web site to learn the truth:
www.vinecom.co.uk

I hope to install the tubes and be back to full power in time for CQWW CW. I will keep everyone informed.

2862. Save operating temperature ACOM 1000

Yahoo group: acom-list (1999 — 2009)
Date: 2008-11-16 23:16:25 UTC
From: pe1czg
Topic: 2862 Message: 2862

Hello all,

Last weekend I did a lot of RTTY contacts and I did run about 400-500 watts out with the ACOM 1000. During many contacts right after each other I saw the temperature going up to 80 degrees and up sometimes. I donot have the extra fan installed yet but I'm wondering what the "save" temperature is to operate for let's say a few hours. The manual does not mention any limits and I guess 80 degrees is still save but I like to hear from others what their thoughts are.

Thanks and 73's Ger PE1CZG

2863. Re: Save operating temperature ACOM 1000

Yahoo group: acom-list (1999 — 2009)
Date: 2008-11-17 08:52:00 UTC
From: Uffe Lindhardt
Topic: 2862 Message: 2863

If you let it go up to 90° you will notice that the fan speed
increases, so ACOM made the balance between the comfort of fan noise
and the air temperature at 90°.

I guess you could step up the fan speed permanently if you study the
schematics.

I would not be so worried. Tubes are cheap, and not easy to kill.

2864. 2000A VSWR/autotune

Yahoo group: acom-list (1999 — 2009)
Date: 2008-11-20 01:52:49 UTC
From: N1EU
Topic: 2864 Message: 2864

Has anybody run into a problem with their 2000A suddenly displaying higher than actual VSWR readings and refusing to complete autotune cycles ("Default: Check VSWR Please Remove Drive"). I know the antennas and connections are all good - my rig barefoot or with my Alpha operate normal/fine.

I've written Stan, but I thought someone else might have gone through troubleshooting this and can pass along some tips.

Thanks & 73,
Barry N1EU

Barry:

What's "higher than actual VSWR readings"?

Every time I have challenged the Acom's diagnostics, the damn amp has proven me wrong. I hate when that happens, but my hat is off to the amp. In my case, there has been some variety of water in the connectors, changed ground system, bad jumper, etc., etc. I'd bet money that "nothing had changed" but when I finally broke down and changed/measured/eliminated segments in the over all cable/antenna system, by Jove the problem would go away.

The barefoot rig may not be stressing the cable/antenna path the same as the amp at QRO.

If the Alpha is on an A/B switch, then swap amps and pull the switch out of the loop.

I know you're an early Acom user and have been around the track a few times....you've probably tried all this, but the Acom just doesn't cry wolf very much.

Will be curious to hear what is causing your situation.

Yahoo group: acom-list (1999 — 2009)
Date: 2008-11-20 10:41:20 UTC
From: N1EU
Topic: 2864 Message: 2866

Thanks Dan, but I'm fairly certain the problem is real. Same results into a dummy load. The issue is more about autotune not completing than VSWR meter, which may actually be okay. VSWR showed 1.2:1 into the dummy load and autotune still gave "Default: Check VSWR Please Remove Drive".

The Alpha is fine with the exact same cabling plugged into it.

I'm in touch with Stan now, running some tests and will report back to the list what the ultimate solution is.

Worst comes to worst, I think I can set everything up ahead of time with DEF tuning and be good for CQ WW. It's just an issue with autotuning - the amp is faulting or anything.

As far as I can tell, I'm back in business with my 2000A autotuning again, thanks to Stan's help.

Stan had me go through a manual tune cycle using the up/down arrow prompts to adjust LOAD/TUNE as directed by the 2000A RCU. It was clear that something was off because following the prompts led me to tune it far away from max output. I believe this symptom pointed Stan to suspect an issue with the phase detector.

He directed me to open up the phase detector cover on the bottom of the 2000A, inspect a few things, clean out any dust, reseat a connector and adjust a potentiomenter back/forth to wipe the contacts. That was basically it. 2000A seems happy again.

2871. IC-7700 and Acom 2000A

Yahoo group: acom-list (1999 — 2009)
Date: 2008-11-21 02:54:27 UTC
From: kamarty456
Topic: 2871 Message: 2871

I used the Icom IC775dsp and the Acom 2000A for about 8 years. Yes I did on occasion experience the dreaded "power up spike" when transmitting. I do SSB and no digital modes.

My Icom IC775dsp is a year 2000 production as is my Acom 2000A.

I just upgraded to the new Icom IC7700. To my relief, the IC7700 does not exhibit any of the "power up spikes" we have recognized with the IC781 and IC775DSP plus other models.

The Acom 2000A seems to have zero conflicts with the IC7700.
I did select MOSFET switching configuration.

A huge sigh of relief here and appreciation towards the Icom engineers finally recognizing and listening to their customers and fixing an aggravating anomaly!

Hello Marty,

Exactly the same on this side! I migrated from the IC-775DSP (with power spikes) to the IC-7700 and have zero conflicts now on the Acom 2000A. It is what you say a whole relief...

With the FT-1000D I did'nt have any power spikes too.

Talking about power spikes: the Yeasu FT2000 does also generate
these at the beginning of a transmission.....aaarghhh.

Ger,
Are you using the IC7700? I have a FT2000D and spikes are indeed there. Most interested if the same case is true with the ICOM?

No Joel, I'm using the FT2000 (not the "D) and this rig is giving a hugh spike at the beginning of a SSB transmission.
So it seems generic then with the FT2K...

Cheers, Ger

Hello Joel,

I am afraid the FT-2000 also suffers power spikes.

As Ger wrote; they are at the beginning of transmissions. Perhaps not all transmissions, but too many. Exactly the same happened with the IC-775DSP.

The IC-7700 produces zero power spikes. In the meantime I made a few thousand contacts with the IC-7700/Acom 2000A combination and all the time with zero faults!

From: Sigismonti Ronald
Topic: 2881 Message: 2881

Happy Thanksgiving to all.
Today one of the ACOM 2000A's here faulted during power-up indicating a message on the RCU stating that the -12V was too low. I'm not sure that the minus sign was part of the message, which disappeared quickly when the amp shut down. Has anyone seen this before? Any ideas? I left a telephone message with ACOM and also with Will, but no reply yet. I guess this is just very bad timing with Thanksgiving day tomorrow.

Any ideas are much appreciated.

Since the manual says that means CHECK THE MAINS VOLTAGE, I'd put a meter on your 240 V main with all the radios on. If it is a contest weekend setup the load may be dropping your line voltage.

John, thanks for your reply. The mains here are above 240 VAC.
Also, there was nothing else fired up when it started happening. I
was hoping this was a tube related problem, but so far you and N4GG
have been the only ones to reply. Guess we will have to use another
amp.

73 & Happy Thanksgiving Day,

de Sig

2884. ACOM 1000 Arc Fault

Yahoo group: acom-list (1999 — 2009)
Date: 2008-11-27 21:07:46 UTC
From: Franki ON5ZO
Topic: 2884 Message: 2884

Acom users, can anyone tell me what is the cause of an 'arc fault'?

I made a new 80/160m antenna (GP with adjustable base matching) and between 3500 and 3560 I get an Arc Fault with 40-45W of drive level from the K3. Above 3600 it never occurs even with 1kW out and 160m is not a problem either.

The root cause is the antenna. Am I correct in assuming that it's a high voltage point in the antenna circuit (not in the amp) that 'flashes over', like the end of a radial or a coax with some VSWR touching the tower? Can this trip the amp into an 'Arc Fault'? I checked for physical damage (burned spots) but I can't find any.

With 35W of drive, I adjust the amp and all is OK. When driving to 40-45, at a certain point, the display shows the amp isn't properly tuned anymore and when displaying the SWR, it goes from 1.2 to 1.3... 1.5... the more I drive and then arc fault. The amp nevers sees an SWR over 1.6-1.8.

All ideas appreciated.

Hello ON5ZO....

I can tell you I have had a lot of experience with "arc faults" with my ACOM A2000.

I had used my Henry 3KA for nine months and never experienced any problem on 75 meters using my 74 ft rotable dipole. The Henry 3KA amplifier does not respond to little things and does not shut down for as we all know, it just keeps going and going. However using the ACOM 2000A and the same antenna I had an "arc fault" problem nearly all the time. It was hard to accept the fact that something may be wrong with the 75 meter antenna. Well, I was wrong for I had used an incorrect size nut on the 75 meter balun and did not know it. Corrected the size nut to the proper screw holding the balun and immediately drove up the ACOM amp to 1,500 watts with zero arc faults.

The ACOM will locate and tell you if something is screwed up and I found this to be true ALL the time. Just for your additional infomation, I had a "forward power spike" coming from my Yaesu FT2000D and shut down the ACOM amplifier. It took me a month with help from ACOM to locate the spike on a scope. It is indeed the fault of some FT2000 units and not a problem with the ACOM 2000A. Some FT2000's do it and some do not but I was convinced it was the linear. I guess it's like having my own RF engineer living with me.

Hope the above helps a little.

Joel, K2QBV

Corrected the size nut to the proper screw holding the balun and immediately drove up the ACOM amp to 1,500 watts with zero arc faults.

The ACOM will locate and tell you if something is screwed up and I found this to be true ALL the time. Just for your additional infomation, I had a "forward power spike" coming from my Yaesu FT2000D and shut down the ACOM amplifier. It took me a month with help from ACOM to locate the spike on a scope. It is indeed the fault of some FT2000 units and not a problem with the ACOM 2000A. Some FT2000's do it and some do not but I was convinced it was the linear. I guess it's like having my own RF engineer living with me.

Hope the above helps a little.

To: acom-list@yahoogroups.comFrom: on5zo@...: Thu, 27 Nov 2008 22:07:46 +0100Subject: [acom-list] ACOM 1000 Arc Fault

Acom users, can anyone tell me what is the cause of an 'arc fault'?I made a new 80/160m antenna (GP with adjustable base matching) and between 3500 and 3560 I get an Arc Fault with 40-45W of drive level from the K3.Above 3600 it never occurs even with 1kW out and 160m is not a problem either.The root cause is the antenna. Am I correct in assuming that it's a high voltage point in the antenna circuit (not in the amp) that 'flashes over', like the end of a radial or a coax with some VSWR touching the tower? Can this trip the amp into an 'Arc

Fault'? I checked for physical damage (burned spots) but I can't find any.With 35W of drive, I adjust the amp and all is OK. When driving to 40-45, at a certain point, the display shows the amp isn't properly tuned anymore and when displaying the SWR, it goes from 1.2 to 1.3... 1.5... the more I drive and then arc fault. The amp nevers sees an SWR over 1.6-1.8.All ideas appreciated.73 de Franki ON5ZO

In my experience anything that can lead to a RF arc will shut down my 1000. Poor antenna tuners, when the feedline is at a voltage node at the tuner, contaminated coax or fitting, or
any easy path the RF can take, will lead to the shutdown. The gradual SWR rise may indicate an issue with a component heating in the tuner (if you use one), or a breakdown due to contamination somewhere.

Thanks ACOM for all the protection.

The Acom fault is actually an excellent too in realizing you have a problem within your RF run!

This can be as simple as a failing piece of coax, such as a jumper, loose hardware on your antenna, or even a PL-259 connector that may have corrosion in its tip!

I was experiencing intermittent arc fault alarms and I finally determined it was my Alpha-Delta 4 position antenna switch.
I replaced it with an ICE 6 position switch and no more arc fault alarms.

Then, I had arc fault alarms again and it was one of those 90 degree PL259 right angle adapters. It looked just fine, it did not show any DC short circuit using an ohm-meter. I put a new one in its place and no more arc fault alarm!

Finally, something as simple as a loose coax connector or cable can cause the alarm. Look at how well your PL259 plugs fit into the female SO239 connector. If the pin is a slightly loose fit you'll get the arc fault alarm.

In summary, consider the arc fault alarm a useful tool in ensuring your RF line is in perfect condition.

From: mgh.friedrich
Topic: 2884 Message: 2889

An 'arc fault' usually indicates an excessive high RF voltage on the output line. The reason for this - for instance - can be a broken coax-line or a resonant antenna-feeding system. I had a problem with the SO239 at the amplifier output and the PL259 connector for the coax, because the tolerance of the SO239 connectors, which my ACOM amplifier is using, seems to me very high. I had to solder the central pin of the PL259 connector to make the pin more thick, so that it just fits into the SO239.

In ur case, Frank, I would recommend to use a heavy 1 KW dummy-load with a long coax and run the maximum power for a test. After this use 2 dummy-loads in parallel or use a coil in serie with the dummy load and carefully stepwise increase its inductivity and by this the SWR without ur antenna. Use a reliable SWR-meter. The test without ur antenna is for separating the cause, because the arc fault detection circuit of ur amplifier may be faulty. If you are able to run the amplifier with full power up to SWR 2.0, it seems that the amplifier is working correctly and then you can move the SWR meter from the amplifier output to the foot of ur vertical and compare the reading. At the foot of ur vertical the reading should be lightly above the former reading at the amplifier output connector.
The increase of the indicated SWR, when the output power is increased, is normal and depends, which diodes ur SWR-meter uses and their linearity. The accuracy of the measured SWR is usually better with high RF-power.

From: billdz.geo
Topic: 2891 Message: 2891

My 2000A has always worked perfectly until today (used it yesterday with no problems). Today, I turned on the power on the main deck and the red light came on as usual. But then, the instant I pressed the red On-Off button on the RCU, the protection light flashed and everything went dark. No fault message.

Connections seem OK. Tried several times (waited several minutes between each attempt), same result each time.

Any thoughts on what could be wrong?

Hello BILLDZ.GEO

I would try to "reset" to full factory default. This assuming you had set up procedures past the way your amplifier came from the factory. In addition to this point call or e mail Will at Acom provided you're in the US.

2901. [Update] Acom 2000A BIAS TOO LOW

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-06 15:24:50 UTC
From: Glenn O'Donnell, K3PP
Topic: 2846 Message: 2901

Hi everyone,

First, thanks a 1.0E+06 to everyone for their help with this problem.

Second, here is what I did so far:

I ordered a set of GU74b tubes from Ron at Vine Antennas in the UK. They arrived in good shape, but it appears the tubes are not the problem. I'll know for sure once I get deeper into this, but I do know that C2 is bad in the lov voltage power supply. Stan LZ1IU from Acom gave me excellent instructions to troubleshoot this.

It took me a few weeks to get to it, since my travel and work loads were horrendous, as usual. I finally took a look at it this morning. The diagnosis told me to look at the low voltage board. It's a pain to get to this board, but I finally did and there it was, as obvious to the naked eye as you can get. The electrolytic capacitor C2 had a big bubble on it. It is clearly fried.

It is a 47 uF/250v device with radial leads (both leads coming off the same end of the can). I'm sure this isn't a Radio Shack part, so where can I get one? Digi-Key has them, but I doubt they'll sell me just one at a buck or two a piece! Maybe it's time for a big Digi-Key delivery from Santa! HI! I better make my list for him!

Thank you!

Hi,

See the attached. I only wanted to prove that certain persons on this reflector have NO idea what they are talking about when it come to Svetlana tubes and their tube production. See the attached photo.
Please mention what you see on the photo on the reflector. Thanks.

Kees,

You have not answered my previous e mail as seen below. A photo of two GU74B tubes? Big deal, can you indicate the answers to my questions for I simply can not see any amplifier owner wanting these to just simply see a photo. I think we all know what the GU74B tubes really look like. For anyone to purchase what you previously said they or I would need to really establish that the tubes were INDEED in the year 2004 and 2008 and new and not just taken off E-BAY or from a person in Europe. Are the tubes NEW???? I think we're all waiting to hear your response....

Joel, K2QBV

Kees,

I guess that anyone that reads what you just wrote won't take anything from you. Do you think what I just asked is unreasonable. So I will ask you the simple question again for this seems like exactly what you did on the YAHOO FT2000 REFLECTOR.

We're all waiting to hear your response for I like I'm sure most people interested are "out of here" as you're concerned. If you deside to answer, please tell us how you are set up to determine a true "matched pair".

Joel, K2QBV

Joel,

Let me set something VERY clear now. Did I mention anything related to the availability of a matched pair? NO! So, your 'simple' question is hereby answered.

Again and please for all our sake read this very thoroughly: The only thing I wanted to point out, and I say it hereby again, is that the GU74B (labeled as 4cx800a) tubes are still manufactured over the last few years at Svetlana SED factory. This despite what some persons on the various reflectors are telling us. Nothing more, nothing less. All fully understood now?

To prove that fact (the availability of these tubes) I have made a photo of some of these tubes and everybody who wants a copy of this photo can get one by asking for it via an e-mail request to my private e-mail address. Exactly that fact, and only that fact, is all there is. The fact that you find the proof by the means of a photo to you is a "big deal", is all-up-to-you my friend.

To answer the generic question of how to see if your set of tubes match in an ACOM 2000A: A good mechanism to determine a good matched pair is quite simple. If the bias current is within 5% difference between the tubes (or better even less) and furthermore can be checked by the temperature difference between the two tubes in an ACOM 2000A during operating should be within a few degrees Celsius, the match is pretty good.

FT2000 group is a totally different story Joel, and has nothing to do with the availability of new Svetlana GU74B tubes topic. Some say on this reflector "Praise the Lord, what a good radio" and some say "it is crap". My personal opinion is right in the middle actually. However, I have no ideas why you mention this reflector site? And please, if you really feel the need, please pin point what you refer to, I for certain have no idea. It does not relate to the topic "GU74B tubes manufactured Year 2008".

Any more questions? Please shoot these to my personal e-mail, thanks!

Vy 73, de Kees.

Hi Joel, Apparently I missed your question?FYI: I have up to now 37 requests for JUST the photo :-) I think I made my point.Like one stated: Seeing it is believing it. It is SO simple. Take it or leave it I guess!Vy 73, de Kees. Member of an all HAM family.AmateurRadio : PA7TWO - M5TWO Locator: JO22jp. To: acom-list@yahoogroups.comFrom: k2qbv@...: Sat, 6 Dec 2008 19:40:45 -0500Subject: RE: [acom-list] GU74B tubes manufactured Year 2008Kees,You have not answered my previous e mail as seen below. A photo of two GU74B tubes? Big deal, can you indicate the answers to my questions for I simply can not see any amplifier owner wanting these to just simply see a photo. I think we all know what the GU74B tubes really look like. For anyone to purchase what you previously said they or I would need to really establish that the tubes were INDEED in the year 2004 and 2008 and new and not just taken off E-BAY or from a person in Europe. Are the tubes NEW???? I think we're all waiting to hear your response....Joel, K2QBVTo: acom-list@yahoogroups.comFrom: pa7two@...Date: Sat, 6 Dec 2008 22:59:10 +0000Subject: RE: [acom-list] GU74B tubes manufactured Year 2008Hi, See the attached. I only wanted to prove that certain persons on this reflector have NO idea what they are talking about when it come to Svetlana tubes and their tube production. See the attached photo.Please mention what you see on the photo on the reflector. Thanks. Vy 73, de Kees. Member of an all HAM family.AmateurRadio : PA7TWO - M5TWO Locator: JO22jp. Kees,

First off, I'm not going round and round with you on these tubes. If you think people will buy these from you because you sent a picture I think you're mistaken.

Allow me to comment on your e mail below AND on your e mail to this ACOM reflector dated December 6th.

You seem to be jumping both sides of the fence for you stated in your December 6, e-mail that "I HAVE STILL SOME OF THESE TUBES AVAILABLE AND THEY WILL BE AVAILABLE BY ME FOR AT LEAST SOME YEARS". You go on to state that "NO PROBLEM SOURCING THESE GU74B TUBES". Now in your new e mail reflector you're saying that you just want to prove that the tubes are available and nothing to do with you providing these. Do you really think people will purchase a tube(s) from a picture??

Merry Christmas.....

Hi Joel,

You already did. Even that you do not understand, it seems. And no I am not the only one thinking this way, looking at the feedback I receive based on your messages.

Seems like you still do NOT get the point! >> T*H*E* P*H*O*T*O I*S* F*O*R* R*E*F*E*R*E*N*C*E* P*U*R*P*O*S*E*S* O*N*L*Y* << I proved the statement of 'no production' is just wrong. POINT! All the rest you imagined is ... AIR.

How many time do you NOT read what is stated? How difficult can it be to understand your own language?

And YES, NOS GU74B tubes are available and will be available for us who are in the need of a spare tube. But hey! Certainly NOT for you as you SHOULD understand by now (Which I doubt :-).

Is there any such thing as a routine maintenance guideline for the
2000A - replacement of several passive components at the 5+ year mark?
There really needs to be for a $6K+ piece of gear that will be in use
for decades.

I know there are also some problematic 100 ohm 1W/3W resistors that
age and mess up some of the internal measurements.

English is not my native language but following the
whole "discussion" it looks like some confusion has come into it.
I understood from all posts sofar that Kees only offers to sent a
picture to whom who are interested to look at a 4CX800 tube
manufactured in 2008 by Svetlana. No mentioning of selling those
4CX800 made in 2008....
I think there is nothing wrong if someone offers to sent a picture to
proof that a tube is still in production. I did bought a GU74 from
Kees (NOS) and this tube is working excellent in my acom 1000 and is
kept as a spare now.

Hopefully this discussion can be closed as it is just don't add any
value.

2919. 2000a fixed - power supply board pics

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-08 14:43:36 UTC
From: Bill Dzurilla
Topic: 2919 Message: 2919

For anyone who was following my prior posts, when I last wrote my 2000a was not working and Will had told me to send the amp to ACOM for service.

The next day Will emailed me and said his engineer in Bulgaria suggested that I replace C22 on the low voltage board before returning the amp. He sent me a pic of the board. I took off the cover and could not even see this board. Searched the internet for info and finally found it. It is buried underneath 2 high voltage boards, almost invisible. I called Will and he explained how to get at it, not nearly as hard as it looks. On the top HV board, pop off all the connectors (no desoldering required) and unscrew the ground lug. Then, go to the bottom of the amp and unscrew the 5 screws to the extenders that hold the HV boards to the chassis. Then the HV boards may be removed, they slip out together. Now you can see the LV board. Unscrew it and with the small transformer, remove the connectors and the board and transformer come out together.

When I took out the LV board, it was visibly clear that C22 was damaged. It was not hard to solder and replace ($3 for a new cap at a local shop). The hardest part was putting everything back together. But what a great feeling when I fired it up and saw that this trusty amp was working again. I am not a good technician and this was a big project for me.

I took some photos while I had it apart and can post them if anyone is interested.

Good job Bill. Those guys at Acom are terrific for their support.
Other manufacturers and sellers could learn some things. I had to
replace my eprom and Will was great help with that project. Your
pictures and narrative might be of help to someone in the future so
putting them on the board would be great.

2924. Acom X-MASS card

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-08 18:27:14 UTC
From: Kees - pa7two
Topic: 2924 Message: 2924

Hi all,

Received today a beautiful season / x-mass card from Acom. Knowing that ACOM reads this reflector, just two words: Thank you!

2926. RE: [acom-list] 2000a fixed - power supply board pics

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-08 21:37:35 UTC
From: Kees - pa7two
Topic: 2919 Message: 2926

Hi Niels,

Do you mean your local shop where you purchased your amplifier, or the Acom factory in Bulgaria?

I had one Acom 1000 with a blow resistor (see report on eHam) and Stanimir from Acom was extremely helpfull with advice and photos, in such a way that I was able to pin point the problem pretty fast and did a repair myself.

On another instance I bought an Acom 1010 for fieldday operations and asked some questions upfront the sale to be able to make the right decission which amp to buy. Promptly I was answered with some very honest views and advice, again by Stan.

At a later point I ordered some spare parts for the Acom 1010 (I always order the obvious items, like RF relays, capacitors and stuff). I was offered very attractive total price including shipment and of course I took the offer. At no way I would have been able to buy these parts cheaper elsewhere, as I found out trying to find the parts on the I-net.

Tell us your story please? (Via private mail or reflector, either of the two is OK for me.)

2930. ACOM1000 Fault

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-10 15:11:56 UTC
From: Brian A.
Topic: 2930 Message: 2930

I was just sitting there with the amp on.

I heard a buzz which sounded like a relay buzzing on/off at a high rate. The lower line of the display was very faint and appears to be scanning at a very high rate.

Now at startup, instead of the count down appearing, the normal after countdown items display on the lower line. Very faint. Like above.

After the countdown finishes, the very faint display remains. The buzz is there too. The buzz is eliminated by pressing the OPER button putting the amp in stand by. The HV reads 3Kv and the temp shows Exh AIR shows 32C with a room temp of 20C.

Any hints on this. I seem to recall a similar situation when I was testing a friends tubes. The bad tube seemed to generate this.

Suggestions?

73 de Brian/K3KO

2931. What is going on during the countdown?

Yahoo group: acom-list (1999 — 2009)

Does anyone know what is going on during that 150 second "warm up" countdown on an ACOM-1000? I know it's getting the tube ready to take the stress of transmitting, but what exactly is it doing electrically. Just making it sit in idle to heat up to operating temperature, or more sophisticated like slowly increasing the heater voltage/current or incrementally increasing the plate voltage?

I know with metal/ceramic tubes it isn't a good idea to turn them on and use them instantly (like we could with the old glass standards like a 3-500Z or an 811A.) Just curious what this "warming up" is actually doing.

I almost always turn on the amp before the rig or looking at the cluster! I must say that is the longest 2.5 minutes in one's life if you do it in the reverse order 'cuz you know there is going to be something you'll see or hear that you can't work with 100 watts.

Anyhow, I'm still curious what's going on during those 2.5 minutes. Maybe it just has to reach idling operating temperature before being driven. There is nothing I can find in the manual other than it's a warm up time.

In the Acom 2000A :
I know that the heater voltage/current is stepped up during this time
to prevent high inrush current. Also there is a warm-up time before
high voltages (Plate/G2) are applied. Could be the same in the 1000/1010

2937. Re: What is going on during the countdown?

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-10 19:27:09 UTC
From: Andrey Stoev
Topic: 2931 Message: 2937

Among the different types of tubes thare two kinds cathodes...direct heated and indirect heated. Among tubes with direct heated cathodes are 572B, 3-500Z etc. In these tubes the cathode is made of toriated tungsten filament, and once power to the filament is applied it takes about one second for the cathode to reach operating temperature and to start emitting electrons.
ACOM 1000/2000 are using ceramic-metal tubes 4CX800A with indirect heated cathode. In these tubes the cathode is a metal cylinder with special oxide coating. The heater is a filament inside the cylinder. Since the cylinder and not the filament itself is the electron emitter, it takes time for the filament to heat-up the cylinder to the operating temperature for optimal electron emission. If the cathode is too-cold (not enough time for heating or low filament voltage) it will get contaminated when the tube is operated and the tube wont produce the maximum power output.

So the short answer - during the countdown, nothing special is going on....power is applied to the cathode heater and the amplifier is simply waiting for the cathode to reach optimal temperature - nothing more, nothing less. The warm-up counter prevents you from using the amplifier before the cathode is heated properly. This is simply the nature of the beast (tube).
An advantage of the indirect heated cathodes is their low inductance (compared to the direct heathed cathodes) which allow for operation at higher frequencies)

Hope this helps!

Not familiar with ACOM 2000. On Acom 1000 the step start procedure last a second or two. Power is applied to the main transformer thru a resistor and in a moment this resistor is bypassed by the step-start relay contact and full power is applied to the transformer. The same transformer (ACOM 1000) is used to supply voltage to the tube heater and for the heater to properly heat-up the tube cathode, nominal filament voltage is required.
As I said in my other post, on ACOM 1000, after the step-start procedure is complete, to prevent power-up inrush current to the fillament, there is no other control over the heater voltages - the cathode is heated for two and a half minutes and then screen (g2) voltage is applied if the amplifier is switched to OPERATE. (full HV plate power is achieved right after the step-start procedure).

I think you will get very much the same answer that I just gave in my
previous posting.
As somebody just said: an indirectly heated cathode needs warm-up time. The
reason
for the heater step-start is that a cold heater wil have very low resistance
and applying
full voltage will cause a very high current the first moments. This can
reduce the life of
the tube due to mechanical and possibly magnetic stress.
Also high voltages should never be applied to a cold tube...they come on at
the end of the cycle..
Peter

Does anyone know what is going on during that 150 second "warm up" countdown
on an ACOM-1000? I know it's getting the tube ready to take the stress of
transmitting, but what exactly is it doing electrically. Just making it sit
in idle to heat up to operating temperature, or more sophisticated like
slowly increasing the heater voltage/current or incrementally increasing the
plate voltage?I know with metal/ceramic tubes it isn't a good idea to turn
them on and use them instantly (like we could with the old glass standards
like a 3-500Z or an 811A.) Just curious what this "warming up" is actually
doing.73, Paul VE1DX

Suspicious message? There's an alert for that.

This has to do with the actual design (mechanical and electrical) of
the cathode employed by different tubes.
According Svetlana's official spec sheet for 4CX800A, warm-up time for
the cathode is 2.5 min with 12.6V heater voltage.

If you really want to make sure that the cathode is heated properly,
it wont hurt to give it another 30 sec before Tx. It might be
beneficial for the longevity of the tube if Svetlana was too liberal
rating the warm-up time. Cathode poisoning (contamination) occurs if
the tube is operated with not-hot-enough cathode. This leads to
decreased emission rate and lower power/shorter life.

This is another reason to make sure that your power transformer tap is
set for the right AC Mains voltage. If the power transformer is set
for 240V (factory default) and you are operating on 220V AC, not only
the plate HV is affected and consequently the power output of the amp,
but also is the filament voltage, causing the heater to operate at
lower-than-nominal voltage, not heating well tube's cathode.

In addition to providing the specified warm-up time for the cathode, there is a proper sequence in which voltages are applied to the control grid, screen grid and plate. If the wrong sequencing happens, the grids [which are very delicate] can see excessive current flow and suffer damage. All of these sequences and timings are specified by the manufacturer, and the amplifier designer generally implements a circuit that simply complies with the spec. All of this is intended to encourage maximum tube life.

RE: [acom-list] Re: What is going on during the countdown?

Among the different types of tubes thare two kinds cathodes...direct heated and indirect heated. Among tubes with direct heated cathodes are 572B, 3-500Z etc. In these tubes the cathode is made of toriated tungsten filament, and once power to the filament is applied it takes about one second for the cathode to reach operating temperature and to start emitting electrons.
ACOM 1000/2000 are using ceramic-metal tubes 4CX800A with indirect heated cathode. In these tubes the cathode is a metal cylinder with special oxide coating. The heater is a filament inside the cylinder. Since the cylinder and not the filament itself is the electron emitter, it takes time for the filament to heat-up the cylinder to the operating temperature for optimal electron emission. If the cathode is too-cold (not enough time for heating or low filament voltage) it will get contaminated when the tube is operated and the tube wont produce the maximum power output.

So the short answer - during the countdown, nothing special is going on....power is applied to the cathode heater and the amplifier is simply waiting for the cathode to reach optimal temperature - nothing more, nothing less. The warm-up counter prevents you from using the amplifier before the cathode is heated properly. This is simply the nature of the beast (tube).
An advantage of the indirect heated cathodes is their low inductance (compared to the direct heathed cathodes) which allow for operation at higher frequencies)

Hope this helps!

Thanks, guys! I knew it had to be along these lines, but I
didn't appreciate the level of detail. Over the years I've seen
various amps (all with metal/ceramic tubes) that had various warm-up
times. I appreciate the level of detail in all of your responses. I
understand the care ACOM has taken in designing these amplifiers
around a great tube. No wonder they work so well!

Line voltage out of range behavoir of ACOM1000 amplifier.

The amplifier was specially suited for use with generators. It would not cease to function with a "soft" AC line and will deliver more than half power at only 75% of nominal mains voltage. It would withstand up to 10 milliseconds (down to zero) voltage drops, and up to +15% line voltage spikes, which is important particularly when used at field days, DXpeditions, and other portable events.

A +10/-25% excursion of nominal voltage is acceptable. For instance, this is 180...264V at 240V tap selection. Nominal taps available are 200, 210,220,230, and 240V.

If you use the amplifier with more than +15% higher manis voltage (above 276V at 240V tap), supply voltages will reach dangerous values and amplifier protections begin tripping. Otherwise severe damages may occure in both: power supply of the amplifier or the tubes.

Lower voltages down to -25% (180V at 240V tap, or 150V at 200V tap) and even short power breaks however are not a problem. Of course, the output will decrease propornionally (down to 600Watts at the lower voltage edge).

The control circuit is happy also with voltage drops of-30%, i.e. below 170V at 240V nominal or 140V at 200V nominal. If the input voltage drops below -30% for longer than 10-20 milliseconds, the control circuit switches off the amplifier in order to save it. Vy 73, de Kees. When talking about ACOM 1000 in particular, plate voltage is applied to the tube the moment, the power is turned ON. There is no control over the plate voltage except for the very brief moment during the step-start, when for a few seconds the power transformer is powered thru the step-start resistor (actually two of those). There is no screen grid (g2) voltage applied during the warm-up. Screen grid voltage is applied when the amplifier goes to OPERATE mode. (It is oFF when in STANDBY)
After the step-start is complete, full plate voltage is applied. Full filament voltage is applied to the tube.
The tube is "shut off" by the deep negative control grid (g1) bias.
And that's pretty much it. Rx/Tx is disabled (bypass mode). At this point there is no plate current.
2.5 min wait to warm-up the cathode. Then OPERATE mode is available.

It is a classic, very straight-forward aproach for start-up procedure.

2946. What goes on during countdown

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-10 23:00:13 UTC
From: Hal Kennedy
Topic: 2946 Message: 2946

What goes on during countdown is the cathodes are being allowed to come up to uniform temperature. There is a filament step-start, but it lasts a fraction of a second - after that the tubes have full filament voltage applied and are simply warming up.

What's really going on:

The tubes in these amps have indirectly heater metal oxide cathodes. In tubes like a 3-500 the filament emits the electronics and gets uniformly white hot nearly instantaneously. In an indirectly heated cathode tube, the filament reaches temperature more slowly because it has the thermal load of the cathode dragging on it - and it's the cathode not the filament that has to emit that 1 amp of current that gets collected at the plate. The cathode will not be white hot - they run dull red. If you run a tube before it stabilizes, some portions of the cathode will be hotter than others. These hot spots will supply all the plate current and that runs a risk of burning a hole through that hotter portion of the cathode since it is current hogging all the plate current. After 180 seconds or so the cathode is uniformly at temperature and there is no current hogging - current is shared equally by all portions of the cathode.

There is no way around it. If you were to jump out the timing relay on an indirectly heater cathode amp and go to full power after a few seconds of turn on you will have junk tubes with holes in the cathodes in nothing flat.

After the countdown hits zero, the servos travel end to end to reset their zero points - they you are ready to work that DX station, assuming he is still there :-)

Yep. But...there are two different things we are talking about:
operability vs. optimum performance/healthy tube/tube longevity.
The amplifier will be operable and it will function at low AC mains...
there is no question about it. Cathode heating is established with a
separate winding on the power transformer and it is NOT regulated!
There are resistors for current limiting but that's pretty much it.
Lower AC mains is directly related to lower heating voltage. If the
cathode is a bit cooler than normal, it will still operate (emit
electrons) but it will be prompt to the so called cathode poisoning
effect, hence decreasing the life of the tube.

>
>
>
> This has to do with the actual design (mechanical and electrical)
ofthe cathode employed by different tubes. According Svetlana's
official spec sheet for 4CX800A, warm-up time forthe cathode is 2.5
min with 12.6V heater voltage.If you really want to make sure that the
cathode is heated properly,it wont hurt to give it another 30 sec
before Tx. It might bebeneficial for the longevity of the tube if
Svetlana was too liberalrating the warm-up time. Cathode poisoning
(contamination) occurs ifthe tube is operated with not-hot-enough
cathode. This leads todecreased emission rate and lower power/shorter
life.This is another reason to make sure that your power transformer
tap isset for the right AC Mains voltage. If the power transformer is
setfor 240V (factory default) and you are operating on 220V AC, not
onlythe plate HV is affected and consequently the power output of the
amp,but also is the filament voltage, causing the heater to operate
atlower-than-nominal voltage, not heating well tube's cathode.de

One more thing ... (again ACOM 1000 in focus) I dont know if you guys have noticed, but ACOM 1000 is "smart" about the length of the warm-up time. If you turn OFF the amplifier briefly, and turn it back ON, the warm up time is a lot shorter. The amplifier actually takes into an account, how long it has been OFF and re-adjust the warm-up time accordingly once it is back ON. If the amplifier has been OFF for a longer period (I have never actually tested how many seconds is the threshold), it goes back to the standard 150 seconds warm-up wait.
This is a nice feature to get you back on track if you accidentally turn it off or change your mind in next few seconds after intentional power-down with the front panel button.
That is what I call attention to detail :-)
(I still keep my old SB-200 as backup amp with its instant warm-up to tackle "that rare DX" before the pileup gets too big while waiting for my ACOM 1000 to warm-up ;-)

2949. RE: [acom-list] Re: What is going on during the countdown?

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-11 12:20:40 UTC
From: Kees - pa7two
Topic: 2931 Message: 2949

It has always been a question: Which tap on the transformer should I use. Tube experts say just slightly under the maximum heater voltage gives a longer life span of the tube. So, I think that the maximum is about 2% under the rated heater voltage is allowed, without damaging the tube under normal operation conditions. If the heater voltage is (much) lower, a lower amount of electrons are released. With too much RF input, the cathode gets poisened indeed.

Over voltage shortens the life span of the heater but on the other hand I question if your (HAM) tubes die more from from over heating or from the on / off cycles. Therefore a few percentage of over voltage is also here allowed I suppose.

Especially during field-day operations the mains voltage may heavily vary and the therefore the correct taps on the transformers are critical on each amplifier. Exactly for that purpose I provided the info.

While thinking about this subject, I have some thoughts about the Acom1010. I explain: The HV is lower under load when compared to the Acom 1000. How about this one? 750 watts is about the maximum of the Acom 1010. Is the tube under much more stress at this point compared to the Acom 1000?

Please share your thoughts on the matter.

Vy 73, de Kees.

Subject: [acom-list] Re: What is going on during the countdown?

Yep. But...there are two different things we are talking about:

operability vs. optimum performance/healthy tube/tube longevity.

The amplifier will be operable and it will function at low AC mains...

there is no question about it. Cathode heating is established with a

separate winding on the power transformer and it is NOT regulated!

There are resistors for current limiting but that's pretty much it.

Lower AC mains is directly related to lower heating voltage. If the

cathode is a bit cooler than normal, it will still operate (emit

electrons) but it will be prompt to the so called cathode poisoning

effect, hence decreasing the life of the tube.

Svetlana's official rating for the 4CX800A is Maximum 800W Plate dissipation and max 2500V DC voltage. As far as I know all ACOM amps were sold with GU74B which is the mil version of 4CX800A. It is actually the other way around - GU74b is the original tube designed for military applications and then they started making the "comercial" version 4CX800A. Both tubes have exactly the same specs, the comercial one ...well looks "comercial" (shiny with nice print).
They have been very conservative on the spec sheet. Knowing well the russian way of thinking (and designing things for that matter) I can tell you (and the practice is showing it too) these tubes can be pushed way beyoned their spec sheet ratings with no ill effects.
To answer your question: It is the other way around - the tube in ACOM 1000 is under more stress and pushed beyoned its spec sheet ratings (2.5kV under load vs. 2.2 kV (specs))to deliver 1000W than the tube in 1010 (750W for tube rated at nominal 780W) and the tubes in 2000 (2x780W to deliver 1560W, amp rated at 1.5 kW).
That beeing said, thousands of ACOM 1000s are performing fine without tube issues - GU74b takes the extra push quite well. Key player is the well deisgned cooling of the amplifier too.
In the "cheap knock-off" of ACOM 1000, the amp Alpin 100 MKII, same single GU74b is pushed even further to deliver 1200W under low duty cycle (SSB) with even higher plate DC.

From: Kees - pa7two
Topic: 2931 Message: 2952

Hi Andrey,

I was refering to the same output level on both amplifiers. So, in other words, by 750 watts output on both the Acom1000 and Acom1010.
Which of the two tubes is under more stress conditions? I reckon the Acom1010 tube is under much more stress because the HV is lower under load.

A lower output can be observed when the Acom 1000 is set on a 230 volt transformer tap and the mains is actually 220v, in example. A 100 volt more HV results in more RF watts output. Sure the heater voltage is lower in this example, not helping as well :-)

The Alpin100 produces more output because the HV is higher!

Vy 73, de Kees.

Subject: [acom-list] Re: What is going on during the countdown?

Svetlana's official rating for the 4CX800A is Maximum 800W Plate

dissipation and max 2500V DC voltage. As far as I know all ACOM amps

were sold with GU74B which is the mil version of 4CX800A. It is

actually the other way around - GU74b is the original tube designed

for military applications and then they started making

the "comercial" version 4CX800A. Both tubes have exactly the same

specs, the comercial one ...well looks "comercial" (shiny with nice

print).

They have been very conservative on the spec sheet. Knowing well the

russian way of thinking (and designing things for that matter) I can

tell you (and the practice is showing it too) these tubes can be

pushed way beyoned their spec sheet ratings with no ill effects.

To answer your question: It is the other way around - the tube in

ACOM 1000 is under more stress and pushed beyoned its spec sheet

ratings (2.5kV under load vs. 2.2 kV (specs))to deliver 1000W than

the tube in 1010 (750W for tube rated at nominal 780W) and the tubes in 2000 (2x780W to deliver 1560W, amp rated at 1.5 kW).
That beeing said, thousands of ACOM 1000s are performing fine without tube issues - GU74b takes the extra push quite well. Key player is the well deisgned cooling of the amplifier too.
In the "cheap knock-off" of ACOM 1000, the amp Alpin 100 MKII, same single GU74b is pushed even further to deliver 1200W under low duty cycle (SSB) with even higher plate DC.

So, I think that the maximum is about 2% under the rated heater voltage is allowed, without damaging the tube under normal operation conditions. If the heater voltage is (much) lower, a lower amount of electrons are released. With too much RF input, the cathode gets poisened indeed.
>

2953. Re: What is going on during the countdown?

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-11 15:59:30 UTC
From: Andrey Stoev
Topic: 2931 Message: 2953

ACOM 1000 with properly choosen transformer tap should show ~2800V plate DC which will sag under load to about ~2500V.
Here is a simple math - 2500V (plate DC) x 0.680 mA (Plate current) = 1700W (input power) x ~60% effciency = 1020W out

I dont have a 1010 and I dont know what is the HV under load and what is the plate current to get 750W out but I could only assume that the stress of the tube will be less simply because to get out 750W out you'll need less plate current and lower DC voltage under the same 60% effciency factor!
In other words, the tube in 1010 is operated within the factory recommended operational specs, while the one in 1000 is pushed to the edge (maximum) specs to get extra 250W out

2954. Re: What is going on during the countdown?

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-11 16:17:20 UTC
From: Andrey Stoev
Topic: 2931 Message: 2954

Sorry Kees,
I forgot to answer this part:
>I reckon the Acom1010
tube is under much more stress because the HV is lower under load.

Not necessarily! Saging of the HV is caused by the plate current,
but the actual sag is related to the "stiffness" of the HV supply.
This has to do with the current capabilities of the power transormer.
If we asume that with no load, both 1000 and 1010 are suppling 2800V
and then under the same load (plate current) 1010 sags to lower
voltage, the input power will be the result from the plate current
and the actual (under load) plate voltage. This does not mean that
the tube is stressed more - the stress is taken by the power
transformer (the transformer responds to the current by saging the
voltage)
The condition you are thinking of (tube more stressed) is if the HV
is much lower in first place and to make up for the low voltage the
tube is pushed with higher-than-nominal plate current to deliver the
same output - I highly doubd that this is the case.
1010 is a cheaper amplifier than 1000 and I think part of the cost-
saving is done with the [smaller] power transofrmer / HV supply.
(lower number of turns / smaller gauge wire for the secondary (HV)
winding)

Hi Andrey,

No problem.

Yes, I do recall a substantial lower HV on the Acom 1010! Not 100% sure... Have to find the documents.

Vy 73, de Kees.

Subject: [acom-list] Re: What is going on during the countdown?

Sorry Kees,

I forgot to answer this part:

>I reckon the Acom1010

tube is under much more stress because the HV is lower under load.

Not necessarily! Saging of the HV is caused by the plate current,

but the actual sag is related to the "stiffness" of the HV supply.

This has to do with the current capabilities of the power transormer.

If we asume that with no load, both 1000 and 1010 are suppling 2800V

and then under the same load (plate current) 1010 sags to lower

voltage, the input power will be the result from the plate current

and the actual (under load) plate voltage. This does not mean that

the tube is stressed more - the stress is taken by the power

transformer (the transformer responds to the current by saging the

voltage)

The condition you are thinking of (tube more stressed) is if the HV

is much lower in first place and to make up for the low voltage the

tube is pushed with higher-than-nominal plate current to deliver the

same output - I highly doubd that this is the case.

1010 is a cheaper amplifier than 1000 and I think part of the cost-saving is done with the [smaller] power transofrmer / HV supply. (lower number of turns / smaller gauge wire for the secondary (HV) winding)

2957. Fixed ACOM1000 Fault (TNX ACOM!)

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-20 13:40:15 UTC
From: Brian A.
Topic: 2930 Message: 2957

The guys at ACOM found a "bad LV capacitor".

9 days door to door! Way to go ACOM.

As an aside.
Put in a NOS GU74B from VINE Antennas Ltd (UK) we got last June. Other
than minor tweaking for the two bias pots, it appears at least equal
to the original tube. Nice to have two working tubes.

2958. Re: [acom-list] Acom 2000A BIAS TOO LOW ****FIXED!****

Yahoo group: acom-list (1999 — 2009)
Date: 2008-12-21 00:41:47 UTC
From: Glenn O'Donnell, K3PP
Topic: 2846 Message: 2958

My dear friends,

I bring tidings of great joy! K3PP's Acom 2000A is back on the air! The BIAS TOO LOW message was the result of a failed electrolytic capacitor (the infamous C2) on the low voltage power supply board. Thanks a 1.0E+06 to Stan at Acom and a whole bunch of you for the help!

The capacitor is a 47uF 250v part. I purchased a fistful from Mouser (part number 75-517D476M250EK6AE3). They were cheap at US$1.72 a piece. I have several here, so if you have the BIAS TOO LOW error caused by C2, let me know and I'll send you one at no charge (while supplies last! HI). Please do not request one as your own spare just in case you "might" have the failure. Please confirm the blown capacitor before requesting one.

The low voltage board is the bottom board in the stack next to the big transformer. It's a bit of a pain to get to it, but feasible with a little patience and care. If you have the C2 failure, it should be noticeable with the naked eye right away. My capacitor had a big bubble protruding from between the leads. There was no doubt it was fried. If you replace yours, remember it's an electrolytic. Polarity matters! Many of us learned this from experience ("experience" is just a euphemism for having made enough mistakes to hopefully learn from them!).

Here are links to photos (courtesy of Stan at Acom). I will try to take a photo of the blown capacitor too. We should probably put them on the Acom list web site with the other photos.

The stack of power supply boards:
http://k3pp.com/Station/Acom2000A/HV&LV_Stack.jpg

The low voltage board showing the location of C2:
http://k3pp.com/Station/Acom2000A/LV_Bias1.jpg

I also purchased a pair of NOS GU74b tubes from Vine Antennas. It turns out that wasn't the problem, but at least I now have the spare set ready to go if I need them. Ron GW3YDX of Vine is a GREAT guy!

This may go down in history as one of the slowest repairs in amateur radio history. The amp went belly up on me well over a year ago (probably over TWO years ago!), but I was so busy with life that I didn't get to deal with it until I sent my plea to all of you last month. I FINALLY got the time to replace the capacitor today!

It's GOOD to be back in business!!

VY 73 ... and to all a good night!

Topic: 1125 Message: 2961

It is very straight forward process - ACOM 1000 doesnt use ALC so you dont have to worry about it. The only thing you need is to connect TX-GND (FT-897) to KEY IN (ACOM 1000)
An optional connection to improve Full Break-in QSK is to connect TX-INH (TX inhibit, FT-897) to KEY Out (ACOM 1000). With this connection, the amplifier will "allow" the transceiver to Tx when the AMP is ready to be keyed. This second connection is not a must, but it will prevent the amp from going into Protection mode, should the tranceiver sends RF before the amp is keyed. Just solves timing issues when switching Rx-Tx at high speed.
On some transceivers the "TX-INH" signal needs to be "pulled up". This is very simple to do - just connect a 10k resistor between TX-INH and +13.8 pin. This will pull up the signal and it will allow the transceiver to TX if the amplifier is not pulling it down to GND. It can be done right into the housing of the DIN connector.
For both connection use shielded audio cable or small coaxial cable (RG-174) with two RCAs on the amplifier side and the DIN on transceiver side. The shield is connected to GND.

Hope this helps!

Hi,Andrey!
Thank you very much for taking your time to write this in a very detailed way, I really appreciate it!
I'll do as you suggested. A couple of hours ago I've got an e-mail from LZ1IU who described the whole process as you did. So that is very kind of you both, giving me a helping hand!
I wish you Happy Holidays, good luck and DX's!

Since that error msg is not in the manual, I suggest contacting ACOM. Did you change tubes? Change the control box? The serial numbers are on the tubes, the amp and the control box. Perhaps the wrong one was returned after service?

Hello John

Tks for rapid answer.

No change for tubes or control box...

Are the Serial numbers the numbers of the tubes ? There are originals
tubes..

In my ACOM 2000 manual, the serial numbers of the fwd and aft tubes and the ACOM 2000 are listed. No other serial numbers mentioned. I don't know why a serial number message would appear if nothing was changed. Contact ACOM.

Good luck. 73 John K1ER

That error comes up when there is a mismatch between the remote control box and the amp control board. At the factory, the remote is tested and packaged with a specific amp, and a number matching the amp is is programmmed into the remote. Maybe some of the amps setup parameters are also stored in the remote. Anyway, this is a programmed value and it is possible for anything that is programmed to become un-programmed. If I recall correctly, I think this is a problem that can be solved without sending anything back to the factory - just contact them. I also believe that using the amp with this problem while you are waiting for a solution won't harm anything.

I agree with Jim. I believe I had this problem several years ago. The fact that I don't remember the exact fix makes me think it was trivial. I believe it involved a reset.

Indeed how could anything have a serial number detectable by the electronics? My point was ONLY those serial numbers were mentioned in the ACOM 2000 manual. I'm not sure why the diagnostics would check serial numbers.

Today I turned on the 2000A.....

I returned to the room a bit later ;
I do not think it powered up at all....

All the LEDSs come up.... then within 3 seconds it goes into fault...
the heater led comes on and the screen says :

IG2 = 199ma
should be zero

what should I look to first ????

I did look to the reflector but could not find anything about IG2 @ 199 ma...
I found low current but not high like 200ma.

I've emailed ACOM, but in the meantime.... Any Ideas ???
Anyone had this symptom ?

tnx
bill ny9h

It's not the number of amps you own(ed) but when you're ordering parts
for your Acom.
This year i ordered a RCU-panel for my 2000 and you will listed so
this year i received a X-mas card of Acom => Thanks Acom !

Wish everybody for 2009 a powerfull and troublefree Acom Year.

It must be a card from the SERVICE dept. They didn't send one to the buyers of ACOM 2000A in 2008. It didn't break so I'm not disappointed.

Well this is almost a cult thing, like a QSL card, at least for those of us who've never recieved them!

But as stated B4, if the amp works, and the support & service have been good, then that's a more important QSL than the paper card (even tho I want one)!

;-)

73's to all

Just for grins here folks.....
Has anyone installed a mini thermocouple digital thermometer
above the tube chimneys to allow you to monitor the
air exhaust temperature in "F"

I just ordered a small unit -40F to +300F

I should have it within 5-7 days.

I'll report back with any comments if no one else has done this.

You ask why? Well, I don't do Centigrade in Arizona..we do Fahrenheit.

I don't know about the ACOM-2000, but the display on the
ACOM-1000 shows both. Right now I'm looking at a display that reads
"Exh. Air 36C 93F." That's from the sensor in the tube chimney, of
course. If you are interested in looking at the exhaust air outside
(just above the protective screen), then you will need a second
sensor and display unit, I suppose.

Hi Folks!
We don't do Centigrade here in Europe either.
We do Celsius.
The Celsius scale was developed in 1742 by the Swedish astronomer
Anders Celsius.
The ninth General Conference on Weights and Measures officially named
the scale
the Celsius scale in 1948 and thus also was adopted by the US National
Bureau of Standards.

2987. [acom-list] Cleaning Valve/Amp

Yahoo group: acom-list (1999 — 2009)
Date: 2009-01-10 22:09:31 UTC
From: trevor dunne
Topic: 2984 Message: 2987

Hi all

Is there a procedure online anywhere as to how to clean the valve/chimney. My amp is a year old and i have it in storage at the moment but would like to give it a clean before i put it back into service.

its a Acom 1000 Btw.

Thanks
Trevor

From: Andrey Stoev
Topic: 2984 Message: 2988

The best way is to use compressed air (from a can). Just blow some compressed air right in the center of the valve's blower fan to loosen the dust and clean the blower first. Do a few short blasts until the blower starts spinnig and the dust comes out. Then turn the amp on the side and open the tube socket compartment - it is located on the under side of the amplifier. The compartment cover is attached with screws. Remove the cover and blow compressed air from the can into the socket compartment and especially in the openings around the valve socket. Before closing the compartment blow some air down thru the chimney (dont remove the chimney itself). That's it! Close the tube socket compartment and blow out the dust from the RF deck and HV supply board before closing the amplifier. Dont remove the valve or the chimney! If the dust is stuck to the silicone rubber of the chimeny you can gently use small soft brush to loosen the dust before blowing it out.

Ola amigos:

O Grupo Araucaria de Dx, visando a continuidade do estímulo a prática do DX estará instituindo o TROFEU MARATONA DE DX .
Utilizaremos as mesmas regras e julgamento estabelecidas pelo CQ DX MARATHON patrocinado pela revista CQ MAGAZINE.
Publicaremos em nossa pagina a regra e condições, no entanto como a competição já é valida para 2009, estamos convocando todos os amantes da prática de DX a já iniciarem a caça as figurinhas.
As regras podem ser acessadas no link
http://www.cq-amateur-radio.com/DX%20Marathon%20Rules%20Dec08.pdf

Os cinco primeiros Brasileiros receberão certificados e os dois primeiros um belo TROFEU.

Vamos ver ser conseguimos colocar alguns Brasileiros no top 10 do proprio CQ DX MARATHONE.

Quem participar do TROFEU MARATONA DE DX do GADX , estará tambem participando paralelamente do CQ DX MARATHON da CQ MAGAZINE.

Poderemos tambem para motivar a todos manter os scores em um link especial.

link para TROFEU GADX MARATONA DE DX

2990. Re: temperature monitor

Yahoo group: acom-list (1999 — 2009)
Date: 2009-01-14 01:34:03 UTC
From: kamarty456
Topic: 2984 Message: 2990

I ordered the Taylor model 9940 digital panel mount thermometer from McMaster-Carr.
They are a delight to do business with. My order was received within a few days!

The range is -40Fto +300F and -40c to +150c
It runs on a single AAA battery

You can get the complete specs from McMaster-Carr their order #4141k11

I have set it to read "F" [Fahrenheit. There is a small switch behind the display.

Now, I set the stainless steel thermistor [for now] laying across the chimney exhaust vent holes.

I have compared the ACOM temperature readings and the Taylor's. Of course the Acom readings on the RCU are an average in 10c steps when viewing the main operating display.

The RCU menu temperature display for each tube's exhaust temperature is also in "C" [centigrade/Celsius] but will track in 1 degree steps for each tube.

I realize the external probe will not track 100% with the internal sensors, but it's not a concern.

I wanted to get a reasonable Fahrenheit display so I don't need a cheat sheet to monitor the amplifier's tube temperatures.

This Taylor 9940 does an excellent job and is very accurate.
The probe has a 10 foot cable and allows a myriad of ways to mount the thermometer.

I am very pleased with this product and its results.

I am not sure yet where I'll permanently mount the probe. I may simply use a small cable tie and adhesive backed mount and then
secure it in between the two chimney vents. I estimate the probe will sit 1/8"-1/4" above the chassis. This will then give me a reasonable exhaust temperature.

Off it went to ACOM .

Will said it was on the microprocessor board,,,
and four chips (including a microprocessor) came back in a plastic
bag., soooo I am glad I did not try to troubleshoot this one.

The turnaround was fast ....and the cost of "out of warranty" repair was
UNBELIEVABLY & ridiculously inexpensive.

ACOM gets my vote.

Most ALCs are imperfect and have a too long attack time. This leads to leading edge power spikes, which are a problem especially with ACOMs, because the protection circuits react very fast.

What you could do is to apply a constant (negative) DC voltage to the ALC input of your transceiver. That removes the problems of the power spikes.

I am not sure if I should post feedback on purchases here but it is related to GU74b so it might be useful to people who are looking to buy replacement for thir amplifiers. I just bought a GU74b from Kees, pa7two. Smooth and quick transaction, using PayPal. I received an email with detailed gettering instructions and pictures of the parcel and shipping receipt. The tube arrived at US East Coast QTH 9 days after it was shipped. Great packaging! Date-code is 1992. NOS tube in the original sealed plastic bag. So far I am happy with my purchase and would recommend it and will buy again! It costs a bit more than what it is offered on ebay but in my case it is more reliable than buying directly from Russia - last time I bought tubes from Russia, it took 2 (two) months after shipping before I received the parcel!

Hope this helps!

The instructions are compilation from a few different sources. I've uploaded the file in the group's file area. Hopefuly Kees will not mind. A very good site is also http://www.ve1dx.net/acomtube/

Here is what I have done - For leads: I soldered wires for the filament voltage (AWG #14) to 2 inch pieces of coaxial braid. Then I folded the braid twice and inserted in heatshrink tubing. Instead of using bare clips (which can short) - I didnt have a spare socket), I punctured the heatshring tubing (with the braid inside) with the tube's filament leads (one should be careful not to damage the lead). This created pretty good electrical connection. Very small insulated clips will work too. Connected the leads to a regulated variable power supply. I used a 12V fan (from computer power supply) and connected the fan to another power supply. I raised the fan with two 1 inch thick pieces of wood. For chimney I used a plastic soda bottle - fortunatly I had one with the perfect size (It was from "Classic Seltzer" water (sold at Costco)). The diameter of the bottle is exactly the same as the inside diameter of the computer fan and by cutting off the top (tapering) portion I was able to adjust the top diameter to fit perfectly around GU74b anode heatsink. IT was a nice and tight fit. The length of the chimney was such so the tubes leads were resting onto the fan's middle section. If needed, PVC tape could be used to aid the seal between the chimney - anode and chimney - fan. Properly cooled tube will get just warm to the tuch but not hot!
The tube MUST be cooled with forced air if gettered outside of the amplifier! Using tube chimeny is the most efficient way! Oversized fan (s) blowing to the sides could also work, but it must be cooled - otherwise the high temperature will destroy the seal around the filament leads and it will ruin the tube.
Here is the gettering schedule I kept:
First hour - 3v filament voltage (cooling fan can be OFF)
second hour - 5v (cooling fan si ON from that point on..)
third - 7.5V
forth - 10V
fifth hour - 12.5V
next 8 hours - 12.5V (nominal is 12.6V but it is better to be a little under than over)
I have checked the tube for internal short, before the gettering started and right after (while it was still hot). When the tube is hot it is normal to see 10-15 MOhm resistance (with DVM) between the cathode and the first grid - electrons are flowing from the hot cathode and the proximity of the grid allows for even the low measuring voltage of my fluke 8050A meter to detect this flow.

That's pretty much it with the gettering outside of the amp. It
allows for slowly raising the filament voltage over a period of time,
which according to some sources would extend the life of the tube.
Crystalization in tungsten filament is addressed this way. I have no
idea about the real-world effect on ramping up the filament voltage
but figured that if nothing else it would not hurt the tube.

Look up VINE ANTENNAS in the UK. This source has shipped over 130 GU74B tubes to America. Vine has designed a complete testing device doing away will craziness associated with getting a good tube. More info is obtained by searching on this reflector for GU74B or my previous e mails to this group containing everything associated with the purchase from Vine. I myself have purchase four tubes for my Acom 2000A and have nothing to do with Vine other than relate where to purchase matched and tested tube(s) that is "read to go". Joel, K2QBV

3002. Voltage Problem

Yahoo group: acom-list (1999 — 2009)
Date: 2009-02-05 14:54:48 UTC
From: hvwhvw
Topic: 3002 Message: 3002

This morning the 2000A shut down from a heater over current limit. The mains voltage indicatated 260 volts which seemed to explain it. However, when I later checked the mains voltage it was back down to the usual 250V. I measured the voltage at the amp with a verified digital volt meter and got a reading of 243 volts. Would analog sensor calibration perhaps be in order? Anyone have any experience with this?

Thanks for your help.

Hello all,

Can anyone give me info if i can connect a Yaesu FT920 with the Acom 2000a without problems ?
Is there no special cable needed to key the Acom so i can use a straight RCA-cable ?
There are 2 possibilities to switch the FT920 on the back in the RY or TR position,is the RY position suitable for the Acom 2000a ?

Hello Hans!

I have a special cable for you, which connects the BAND DATA of the
FT-920 with KEY IN and KEY of the 2000A.

With this cable the FT-920 will transmit AFTER THE 2000A has received a
PTT-command.

Heeee,

Thanks for reply Hans !
Is this cable really needed because it will be probably used for one
time with my Acom 2000a.
Please give me the price with shipping to me if you want.

I saw that there is a RCA on the backside of the 920 with a RY and TR
possibility and that RCA will i connect with the Acom,that was my idea.

Hans

3006. 9000mp

Yahoo group: acom-list (1999 — 2009)
Date: 2009-02-07 22:26:23 UTC
From: paul glassman
Topic: 3003 Message: 3006

a little follow up. last week i asked about connecting the alc to my 9000mp. didnt want to kick 400 watts into the 2000a. i called will and he said... dont worry and dont use the alc. if you fire to much power into the 2000a it will just protect itself and go off line. the combination works like a champ. only one time during the past week has it gone into the protect mode.

I don't know who the moderator of this ACOM list is, but perhaps they could allow users to upload files. That way Tony could upload them here instead of sending copies to all who requested them. If this group is like other Yahoo groups, all a moderator has to do is to set it to allow members to upload files. (I saw the pictures, and they are impressive.)

I purchased a new ACOM 1000 to replace my old L4B
The exciter is a Kenwood TS940s.
I made the connection and the ACOM1000 works fine on SSB but
on CW, at first dit of the keyer, the ACOM goes into protection.
By the way, if I switch on the SEND button of the 940 before I start
handling the keyer the ACOM 1000 does not go into auto-protection.
What am I wrong ??
Thanks
Ed

Sure sounds like a timing thing, Ed. I've had both (a TS-940) and an ACOM-1000, but not at the same time. My guess is that the TS-940 is sending RF out just before the relay line put the amp in transmit mode. I haven't had the TS-940 for 10 years so my memory is fuzzy as to where the amp XMIT signal comes from on the back of it. My guess is that with SSB, pressing the PTT on the MIC doesn't generate the same rapid rise in RF out (and thus RF in to the ACOM) as the first part of the CW wave rising. Just a thought. I don't know how you can get around it (or prove that this is the cause.)

Perhaps one of those external amp relay buffers between the rig and the amp, but it would be a shame to buy one if this isn't the problem. Is there anything you can adjust inside that trap door on the top of the TS-940 to change the CW timing slightly? I just can't recall how configurable the TS-940 is.

is it possible that you have the drive set to high and the 940 is sending a 200 watt spike to the amp???

Have you tried to drive the amp in Semi Break In instead of Full Break In?
Sounds like a timing issue with the 940 delivering power before the amp itself is keyed.

I purchased a new ACOM 1000 to replace my old L4B
The exciter is a Kenwood TS940s.
I made the connection and the ACOM1000 works fine on SSB but
on CW, at first dit of the keyer, the ACOM goes into protection.
By the way, if I switch on the SEND button of the 940 before I start
handling the keyer the ACOM 1000 does not go into auto-protection.
What am I wrong ??
Thanks
Ed

This could actually be two different problems....
It could be a timing problem or it could be a power spike problem in the 940.
I do not know the 940,- but a lot of rigs put out a short spike of much higher power
than the drive setting says at the first few milliseconds of TX.
CW is much more prone to do so than SSB in most rigs..for several reasons.
The protection circuitry in the Acom is very fast and will see this as overdrive and
trip the amp.
This problem is most easily fixed by applying a fixed bias to the 940's ALC input.
This will control the spike-problem...and it can be done externally at low cost.
A timing problem can be fixed by connecting a cable from key OUT on the Acom to
TX-inhibit input on 940 ...if it has this input... I assume the Acom 1000 has a key OUT
as well as the key IN that is used to put it in transmit.
Using key OUT to TX-inhibit on the rig will prevent the rig from transmitting before the
Acom
tells it all is ready.
if the 940 has no tx inhibit is should be very easy to fix this....easy job for a skilled
person.
As I do not know the 940 I can not give you specific circuitry advice on this.
It is usually just a matter of moving a wire and installing a back panel connector...or use
a "spare" one (that is: one you never use anyway)
By the way, my IC 765 and Acom 2000A shows no such problems...but others have had
it with the same combination and fixed it as described above. Should work with TS940 as
well....

The 940 wasn't know for a spike problem. However, the transmit relay could be slow. I like using the "transmit on" signal that is on one of the DIN plugs on the 940. Use this to drive a power mosfet. This would give you more overhead from when the 940 tells the amp to turn on and RF comes out of the 940.

I have a 1000, it is great! I'm considering moving up to a 2000a. In my QTH shack I'm using a straight, window line fed dipole for antenna and have a Palstar AT-Auto tuner backed by my Acom 1000 and a Flex-5000a. I can work all bands today with in barefoot with amp. Do I still need the AT-Auto if I upgrade to the 2000a and work barefoot or amp mode?
Thanks,
Randy

Hello Randy,

It depends on the SWR of your dipole whether you will need a separate
antennatuner or not.

The Acom 2000A is able to "tune" antennasystems with a SWR of <1:3.

Randy, The 2000A does not have a built in antenna tuner. It has a Pi-L output network like most any other amp, that will auto-tune up to about 3:1 SWR safely. The amp cannot be used as an antenna tuner, in-line or off line.

Yes. The Acom 2000A will not work as a tuner.
And even in bypass, if the SWR is too high it will beep when you transmit and ask you to reduce power. The protection circuit will sense the high voltages that come with high SWR.

3030. ACOM1000 tube life?

Yahoo group: acom-list (1999 — 2009)
Date: 2009-02-19 09:02:47 UTC
From: Brian Alsop
Topic: 3030 Message: 3030

Purchased a used ACOM 1000. It was checked out by ACOM before put into use.

At first it operated perfectly getting nearly a KW output on all bands.
Solid 12db gain on HF with 13.5 db gain on 6M.

Usually ran at about 600-800 watts out with about 40-45 watts drive on
HF bands.

It began to require more and more power to drive on HF bands. 6M output
maxed out at about 700 watts. More drive produce a 800 ma plate current
trip. The gain dropped to 11.5 db on HF and 12db on 6M.

Purchased a checked out and burned in final from Vine electronics. It
brought back the original output levels.
(Bias was carefully adjusted by the prescribe procedure via the two pots.)

Now after about 4 months use, I'm beginning to the same problems. More
drive required on HF and 6M output dropped.

Any tube guru's out there care to comment on what might be happening.
It is used mostly on CW/RTTY.
Line voltage is 240 +/- a few volts.

Hi Brian,

Sounds like a case of the first tube wearing out (normal) and
the second one having been in a weakened state due to age. It tested
out fine at the store, and worked for a few months, so there would
have been no way to know ahead of time. This is exactly what I've
seen with soft tubes in other amps, anyhow. They roll off at the
higher frequencies first. I'm still on my original GU74b, but
whenever it goes, I will find out for sure if the NOS replacements I
obtained are really as good as the original. They tested out fine.
but who knows how long they will last?

I doubt if there is anything wrong with the amp itself. Try
another tube, I guess. It's frustrating. I went through seven or
eight 811A Chinese clones several years ago in an AL-811H and finally
re-tubed that amp with clone 572Bs, which fixed the problem.

As far as I know, there is no replacement for the GU74b/4CX800A
other than to try another NOS one.

Hi Paul,

Yep, it's like trying to find a "good" used car.

When I had an ACOM-2000, ACOM replaced three bad tubes under warranty
until I finally got a good set.
The 2000 was nice but didn't have 6M. I do miss the extra 3db on RTTY
and LF bands.

What drives us usually rational people (?) to knowingly buy an new
amplifier when it is also known that the manufacturer can't supply
replacement tubes? It's insane.

Well . . . I dunno! I did a lot of research and it seemed to me that ACOM-1000s and been bounced off rocks from DXpeditions where it was -40 C to others where it was +40 C and it kept on ticking. I looked at the competitors who sold comparable quality amps but that had $1000+ priced tubes (like Eimacs.) At the time, there were tons of $100 NOS GU74bs . . . you could literally buy 10 NOS GU74b tubes for the price of a single 8877, for example.

Soon after I got mine, the supply of NOS GU74b tubes dried up, Why and how badly has been discussed to death here and elsewhere. The fact remains you can't get a brand new one straight out of the factory, and I don't care what anyone says to the contrary. You can't.

However, it's a fairly small price to pay (in my view, anyhow) for otherwise the best amp on the market. I loaded up on NOS tubes soon after I got it and I *think* I have enough spares to last me the rest of my days. If one or two of them fail, then it's still cheaper than a 8877 or a 3CX800A7 by a factor of 8-10. Sure, it will be frustrating to have one of those last just a few months and another last 5 years, but that's the way all NOS tubes are.

In 1991 I had a TenTec Centurion. Eimac stopped making 3-500Zs shortly after I got it. So . . . I tried the NOS market and got a couple of Amperex ones. They turned out to be OK. Sold it to a fellow DXer and he's stuck now buying Chinese clone 3-500Zs. They (like ALL glass tubes) have a half life of a month! There is no permanent solution.

As far as the 1000 goes compared to the 2000, I would love to have an auto-tune amp that put out 2000+ watts, but it's just too expensive, and like everything else, the failure rate is directly proportional to the number of parts. I still believe the ACOM-1000 is the best buy of any amp on the market today taking all factors into consideration. There are places were a 2000 is "necessary", like contest stations that need to click on a spot for a multiplier on another band and be there in 100 milliseconds, all tuned and ready to go. I'm a DXer, not a contester, and I can afford the 10 second delay to switch bands. The extra power would be nice, especially on the low bands, but I can usually get through with 1000 watts.

A lot of rambling here. but the bottom line is playing around to get a good NOS GU7b is a weakness with ACOM amps . . . and about the only one I see. For me it isn't a show stopper.

73, Paul VE1DX

3034. Acom 1000 and TenTec Orion I

Hello everyone
I have a question about the connection between the Orion I and Acom 1000 PA.
More specifically if you have only used the connector Key In on the Acom and AMP KEY 1 on the Orion or if it is better to use the pair of connectors
TX OUT 1 / TX EN 1 on the Orion and Key In and Key Out on the Acom.
From what I read on the manuals of these devices would appear that the second solution is better for QSK.
Thanks
Franco I6QFZ

Hello Irwin. I've had my K3 and ACOM 1K working together since 12/08 with no major issues using either QSK or regular delay. I use the standard menu settings on the K3 for amp operation, and no K3-ACOM ALC control cable as recommended.

The only issue is that the K3 is currently prone to periodic power spikes from a lack of internal ALC control under these conditions:

1. Doing a SWR sweep across the band in SSB, CW, or DATA mode, w or wo the amp connected. That operation generates a power pulse from the K3 every 5-7KHz as the ALC responds to changes in LC by frequency.

2. Driving the K3 with a remote foot switch plugged into the rear straight key port while in SSB mode and CONFIG:SSB+CW enabled, and adjusting the K3 output power to tune the amp. Only use the TUNE button for now in SSB mode. However that method works ok in CW or DATA modes. Elecraft is aware of these spikes and may fix.

In other words, don't run the amp (or any amp) in power mode (switch to standby) while doing the above as it doesn't like the K3 generated temporary power spikes.

Gale,

Thanks for your feedback. Greatly appreciated.

Where do I purchase or get a schematic to build the K3-Acom ALC cable you mentioned. I hope to use the K3 tune button to tune my amp and for my auto tuner with it set for a power of less than 50w. I am do a lot of contesting and will quickly change bands to chase mult's.

Thanks, Irwin

Hello Irwin. No interconnecting ALC cable is required between the K3 and ACOM 1000. The ALC problems I refer to are internal to the K3, and control the K3's PA output. The K3 manual does address an ALC inter-connect cable if you wish to operate with one for some reason between the rig and the amp. Read Elecraft and ACOM's cautions and recommendations.

The issues of concern are power spikes from the K3 that upset the amp via overdrive when operating only under the conditions I described. Avoid the conditions, and you will have no problems.

Hello:

Today my ACOM 1000 fault. On 7 Mhz i can´t excite the amplifier with more than 36 watts. This power generate (after turning on the amplifier) a Plate current= 700 mA and forward Power=892 Watts (swr 1:1). If i try to axcite the amplifier with more power, the "Warning: plate XXXmA" come on the display (current over 700 mA) and one time an "Autoprotection SB06" alarm turn the linear off .
In other bandas the amplifier works well, it fault only on 7 Mhz. I bought the amplifier 3 months ago, so the tube is OK.
Any idea about this bug?

Best regards

Javi,

This is just a guess, but I had a similar
problem on 50-MHz and it was RF getting into the
amp. It sounds strange, but the cure was an RF
toriod on the AC MAINS power cord. The RF was
causing the microprocessor to act up. (i.e. the
microprocessor may be fooled into thinking the
plate current is too high when it really is
not.) Make sure the amp is well grounded and try
all sorts of RF suppression. Even a coaxial
choke "balun" at the antenna feed point could be the solution.

If it is not RF, then it is best to talk to
ACOM as it is still under warranty.

Are you using the tuning indicator to provide a proper loading of the PA ?

This sounds like the kind of error you could get if you were tuning for max. gain.

You should not vary the input power to the PA, but rather use the attenuator when tuning. When you switch in the attenuator the tuning indicator shows automatically.

Hello:

I think it will not be caused by RF. 3 moths working OK and now not..... It it grounded (cheked all conexions) and there are five TDK ZCAT3035-1330 ferrites on the AC power cord. I use the tunning indicator to load the PA, and for the load i use 20 Wtts from a kenwood TS 480 SAT (the ACOM menu displays 17-18 Wtts) after that i put the transceiver in RX, change the output power to 50 Wtts and Adjust again the PA. I use this power to excite the PA (Kenwood=50 Wtts and ACOM said "drive RF power 47 Wtts").
It generate 1 Kw on all bands.
I checked all bands and work s correctly, but the bug is in 7 Mhz and 10 Mhz..... THE SAME SWITCH POSITION. On 7 mhz and monoband rotatable dipole and 10 Mhz inverted V dipole Monoband i found the same problem..... Maybe it will be in the specific circuit for 7,10 Mhz.....
if i move the triangule (on the tunnig indicator) a little bit to the right of the center using the LOAD Knob, the plate current goes down and i can use more drive rf power, but the Pa is not loaded correctly.
I will email the dealer, meabe they have an good idea of the bug......
Best regards.

To verify whether it IS or IS NOT a RF Problem, just connect amplifier
with a short and well shielded and correctly soldered coax jumper
to a 50 Ohm Dummy Load capable or handling full RF Out of the ACOM Amp !

My ACOM 1000 does not like more than approximately 700 mA plate current. I try to run it at 650 or less via the plate current monitoring mode, or the Tuning indicator. The amp may prefer a load that may not be 1:1 SWR for some reason according to ACOM for max out. No bugs, just the way they perform in my experience.

Sounds a bit high on the price unless the owner has replaced the 4CX800A (GU-74B) tubes in it or gives you a spare set

Also, if you work CW, sometime in 2002, ACOM isolated the Vacuum Relay and made absolutely QUIET QSK as opposed to earlier year models 1999 to 2001 and maybe early 2002 where QSK mode was VERY NOISEY with much clicking noise from the output relay

The price of Used ACOM 2000A models has gone up almost $1000 (U.S.) ever since ACOM raised prices over the past 3 years

Last I heard, a NEW 2000A was $6800 (U.S.) !

3053. Assure me the silence of 1000

Yahoo group: acom-list (1999 — 2009)
Date: 2009-04-06 19:32:57 UTC
From: oh2bps
Topic: 3053 Message: 3053

Hi All

Please folks. I've read the reviews and found that Acom 1000 is very silent amp and I really need one that is silent.

I have heard people say that this xxxx is so silent that one can't hear it but placing ear on the rig.... well, my piece of that rig must have been a lemon - it was like a leaf blower.

So, assure me that Acom 1000 is so silent that my PC is topping it :)

Anyone - AL80B vs 1000?

Best 73
Ben

> So, assure me that Acom 1000 is so silent that my PC is topping it :)

Since I put an extra blower in my PC case it makes much more noise than the ACOM 1000.
The amp is really quiet for a kW amp and the fan speed is always constant no matter what mode or keying cycle.

The fan in the 80B is fairly quiet but the relay noise will drive you nuts...
The 1000 will be working long after the 80B has expired..

Topic: 3053 Message: 3057

Acom 1000 is very low noise, compared to a budget amp like AL80B, but it is not "silent". There is no high power RF amplifier that is silent. Big fans that move a lot of air make noise. If you don't want to hear the noise, get an Acom 2000A and remote mount the RF deck away from your shack so you won't hear it.

Use headphones.

73,

Bob W5OV

OK guys.... Seems that A1000 has enough low fan noise levels compared to my previous SB-220.

I can take a steady low/lowish noise from the amp but not from the rig, especially when purely RX'ing (bye bye ft2000) :)

I think my choise is now clear - TNX

3059. Acom 1000 failure

Yahoo group: acom-list (1999 — 2009)
Date: 2009-04-12 11:53:04 UTC
From: pe1czg
Topic: 3059 Message: 3059

Hi all,

This morning I had a strange failuer with my acom 1000: after the 2.5 min heating period I got A SB0 something error on the display and the unit was shutting itself down. I only could see the SB0 and it was too fast to see the rest. The auto signature was: 1ASB2B. Anyone know what this means and also where could I find the excel application from Acom to "decode" the signatures? I can email ACOM but maybe someone has it alreday and could forward it to me.

Thanks, 73's Ger PE1CZG

Ger,
According to the downloaded handbook I have with me-your indication 1ASB2B
1A is the event that is being reported
SB2 means tests made during standby after the warmup period
B means output relay closed

I think its trying to tell you the vacuum relay is faulty,at least thats my interpretation.
Good luck!

regards, Steve G8LIK

Bob, yes indeed!
However if the relay is faulty and out of warranty I note that Max Gain Systems in the USA sell brand new Gigavac GH-1 26V coil vacuum relays,the equivalent to whats in the Acom at $69.
I know they ship fast internationally +reliably as I bought some ex equipment but hi pot tested (Jennings) spares from there before....just in case.

hello Tony,
same failure here. Within the very last minutes of VK9m activity, the relay stuck after several failure messages that appeared from time to time and went off after switching between STandBye and USeR.
So I need the procedure also. Please keep me informed how to replace the relay(s).
Thank You in advance.

Tnx Ted,
I sent a note to Acom too. Want to find out if it is recommended to change the input relay at the same time with the cover off.
The amp is a pain to get to as it is mounted high on a shelf that is hanging from the ceiling in the basement. It is mounted directly under my feet when operating by about 3' below the shack floor. I only have the RCU in the shack.

Checking the reflector content for the given failure message, I just found the message below, given by Dick, WC1M in 2005.

Yes, I'm using CW BreaK-in and QSK full.

How to use VOX & CW ?
Anyone has good experiences with VOX & CW ?

Talked to Acom. Will said it most likely is the vacuum relay. There isn't a procedure for replacing it. But where it is located is quite visible and should not be a big problem as long as you reconnect the wires properly. He said typically the input relay does not fail and no need to replace it.
If pictures are needed I can take some when I do this and post them.

Tnx Ted,
I sent a note to Acom too. Want to find out if it is recommended to change the input relay at the same time with the cover off.
The amp is a pain to get to as it is mounted high on a shelf that is hanging from the ceiling in the basement. It is mounted directly under my feet when operating by about 3' below the shack floor. I only have the RCU in the shack.

Both Sig and I have replaced our vacuum relays, Tony. It is not
difficult, but a little tedious. Shouldn't be a problem for you.
The worst part is desoldering the lugs on the relay to get it out,
and reverse soldering in the new one.

I can't recall, but I think I have a Kilovac HC-1 in mine, and Sig
replaced his HC-1 with a Jennings RJ-1A.

It's been many years since I replaced my relay, but my dim memory is
to use a relatively high wattage soldering iron and minimize the time
spent soldering the braid to prevent the braid from soaking up too
much solder, which would cause it to become stiff and compromise the
noise isolation.

Along these lines, isn't running full QSK a recipe for wearing
any relay out? I never have with any amp. I tried it a few times
(sent my call 2-3 times to see how "bad" it was) and it seems to me
the relays are going crazy. Sure, it's good to be able to hear
between the code elements, but I wonder if it is worth the wear and
tear on the rig and amp?

I certainly will NOT do this with my ACOM. Wondering if it is
as big a factor as I think it is. A lot of people say they couldn't
operate without full QSK. I work 80% CW, and I feel it isn't necessary.

Hi Paul,

If I am running I don't see a need for QSK. In fact I think it is a distraction when running. However, when S&P and working DX I find QSK very helpful. It saves time and gives you a feel what is going on. You can tell when the other station has come back to someone. You cause less QRM using QSK.

What stress are you talking about? Other than the input and output relay cycling a lot, I can't think of any harm to the amp.

I have one of the first 2000A's that came to the states. So after all these years I need to replace a relay that is much less than $100 new. Sounds like quite a good deal for all the use of the amp.
In regards to the clicking of any relays, my amp is in the basement so I don't hear anything. It is very quiet in my shack using QSK.

Sending VE1DX switches the relay in the rig and the amp twice,
once to put things in XMIT and once to go back to receive. ..._ .
.---- -.. -..- switches the relays 34 times. It's not the clicking
that concerns me. It's the excessive switching that the relays in
the radio and the amp have to do. A 17:1 increase just to send my
call can't be a good thing from a mechanical point of view.

I understand it's nice to be able, in a DX pileup, the hear the
DX send N2 instead of VE and then I can stop my transmission without
completing my call, but at 24-25 WPM it doesn't seem to make a lot of
difference. It is better, I agree, but I question whether it is
worth the excessive wear on the relays, that's all.

They may be inexpensive, but it would take me a week or two to
acquire and replace one in the ACOM. I don't know what I would do
with my PRO3 . . . I'm not inclined to take it apart and replace the
relay in it. I somehow can't get my mind around the idea that full
QSK in not abusing the gear. Things break and wear out, but there
seems to be no need to hasten the process by a factor o 15-20, if my
theory is correct. Maybe it isn't, but I don't want to chance it.

Do I have this wrong? All modern gear says "supports full
QSK." Does that mean it is no harder on the equipment than not using
it? No one has ever answered this.

73, Paul VE1DX

Hello All,

I operate full CW QSK most of the time.
Even during contests. I couldn't do without it.

For that reason I have replaced the vacuum relay
3 times so far. It usually lasts about two years of
QSK operation.

Attached is the info I received from Stan at Acom
regarding the relay replacement along with some pictures...

I recommend you use a vacuum relay from Gigavac.
They sell a brand new relay, to hams, for about $75.00 Bucks.
Cant go wrong. You don't have to worry about using a second
hand relay... Check the below web site...

http://www.gigavac.com/products/relays/ham/index.htm

---

1. Several important rules must be observed when handling the relay:

a) Do not force or stress the relay leads during unsoldering and soldering. Use a solder vacuum pump during unsoldering to remove all the solder before taking off wires from the relay leads.

b) For contact leads use a powerful soldering iron of 100-150W, with a massive copper tip, since the relay leads and ceramic draw much heat. The soldering tip temperature must be between 280 and 350 degs.C (535-660F). The soldering time must not last longer than 4-5 seconds after the solder has melt, and must be less than 10 seconds totally. Otherwise you risk overheating the meatal-to-ceramic vacuum-proof joint and destroy the relay. Wait minimum one minute after each soldering to let the relay case to become cool. The resulting joint must be lustre and without sharp tips. Use only non-corrosive flux. You could use the old relay to try soldering method on it before doing on the new one.

Clean the ceramic surface with alcohol but not before it becomes cool.

c) For coil relay leads a small soldering iron would be suitable. Nevertheless, be very careful because the plastic coil frame is fragile and could be easily broken. The problem arises while one tightens the nut, if the tool would slip suddenly. Anyway, they offer spare coils for Jennings and Kilovac. The Russian pins are much stronger.

d) When tightening the relay nut, the maximum permissible torque is 10N.m (about 86 Lbs.inch). When you have no dynamometric wrench available, please note and remember how do you feel the force you have used while loosening the old relay. Use a similar force for the new one.

e) The contacts layout of the Russian relay is as follows:

- Orient the relay with the contact leads towards you. Rotate it with the lead which is differently shaped to the bottom (it seems like a soldering lug and is labelled with "3" on the ceramic surface). This is the normally closed (N.C.) and it corresponds to the KILOVAC "A3". Connect it to the central wire of a neat coaxial cable, connected via a BNC connector to the tube deck. This is the RX- and STBY- RF bypassing path.

- The upper-left is the common (COM) and is labelled with the Cyrilic/Greek Pi (it seems like inverted U). It corresponds to the KILOVAC "A2". Connect it to the central wire of the current transformer (located just below the relay).

- The upper-right is normally open (N.O.) and is labelled with "P" (followed by the serial Nr). It corresponds to the KILOVAC "A1". Connect it to the amplifier output, i.e. the lead that comes from a horizontally-installed ceramic coil (the L-branch), and a ceramic choke (located above the relay).

2. In order to remove the defective relay please do the following:

a) Unsolder the silver plated copper braids from relay contacts. Using a pair of nippers, clamp the braid closely near the soldering in order not to let the solder to be sucked through the braid. The braid would become hard otherwise, thus the relay contacts would be stressed after the solder congeals, also the relay clicks will sound stronger with a hardened lead.

b) Unsolder the two coil relay leads.

c) Loose the relay nut and remove the relay from the little sub-chassis.

3. To install the new vacuum relay please do the following:

a) Mount the new relay, directing its common contact to point to the current transformer. The small tooth on the relay metal case must coincide the cut made for it in the aluminium chassis. Don't forget to thread the washer, then carefully tighten the hexagonal relay nut. Always beware of broking the coil leads if you knock it occasionally with any tool.

b) Solder the short copper braid (from current transformer lead) to the common contact and the longer one (from the ceramic choke) to the normally open contact.

c) Solder the central wire of the RX-bypassing coaxial cable to the normally closed contact. Check whether the cable grounding lug needs to be tightened.

d) After the relay becomes cool, clean its surface from flux remains using alcohol.

Ted,

Just curious what you would estimate that the impact would have been, had you used semi-break-in instead? In other words, what if you *had* to do without full break-in? Less countries worked, lower contest scores?

The few times I have tried QSK, I found it so annoying that I don't even think about it. I do set the delay on semi-break-in to be very short so that when I stop sending, it goes back to receive (between words) but not in the middle of a character. I am probably in the VE1DX camp on this issue.

I have operated lots and lots of CW contests and worked lots of DX over the last 35 years and have never thought that using full break in would have made any improvement at all. I never use VOX on SSB either. I use a footswitch for SSB.

The vacuum relay in my Acom 2000 had to be replaced only once after about 10 years of heavy usage on all modes in multi-ops where it withstood a lot of abuse.

73,

Bob W5OV

Hello All,

I operate full CW QSK most of the time.
Even during contests. I couldn't do without it.

For that reason I have replaced the vacuum relay
3 times so far. It usually lasts about two years of
QSK operation.

Attached is the info I received from Stan at Acom
regarding the relay replacement along with some pictures...

I recommend you use a vacuum relay from Gigavac.
They sell a brand new relay, to hams, for about $75.00 Bucks.
Cant go wrong. You don't have to worry about using a second
hand relay... Check the below web site...

http://www.gigavac.com/products/relays/ham/index.htm

Bob,

You have to use QSK in a couple dozen CW pile ups to gauge the
effectiveness. It appears to me that QSK is becoming a necessity (like
full legal power) these days.

Here's what I see when using QSK to listen to the pileup while listening
to the dx.
1) Group 1 - non QSK guys -- calling too long, calls timed all wrong.
2) Group 2 - QSK guys who send their call and if don't make it send the
call again and again. This eventually results in snagging the DX. In
other words, they know instantly that the DX didn't come back to
anybody-- exactly the time you want to be dropping in your call.
3) Group 3 - Lids QSK or not. Include those using code readers here.

With more and more guys appearing in group 2. It almost becomes a
necessity to be competitive. It is a brave new world. What was
successful 5,10 or 20 years ago isn't necessarily what it takes now.
The other alternative is to have a superior signal.....

Incidentally the GIGAVAC site quotes a lifetime of 2 million ops for
their vacuum relay. A rough hand calc indicates thats like dropping
your call in about 60,000 times.

3085. Re: 2000A - relay alarm

Yahoo group: acom-list (1999 — 2009)
Date: 2009-04-15 12:40:32 UTC
From: Hal Kennedy
Topic: 3066 Message: 3085

I was really curious whether the relay failures were related to QSK operation, but I think the recent posts tell the story. I once lost a relay in an Alpha 99 (same relay, same amp for that matter), even though I never operate QSK and replaced it with a Kilovac. The two 2000As here have thousands of hours on them and one is on its third set of tubes, but both still have their original relays. My own view is QSK is not "abuse" per se, just "very heavy use." Hearing the relays banging away in the transceivers and the amps gives me a bad feeling, and I don't want to change the T/R relays in my MPs, although changing out the relays in the amps is not a big deal.

If you operate a lot and it's all QSK, you might as well keep a spare relay along with a spare set of tubes. You will need it. I wonder how many of us are hot switching, which will get the relays stuck in a hurry? My experience is the second RCA jack control line on the back of the 2000A - the transmit inhibit line - is not used in most shacks. It's not used in mine. It's there to prevent hot switching.

Brian,

My MFJ pocket code reader takes great umbrage at that
comment! I'm a number 3 above. :-)

Seriously, how does sending K3KO without QSK differ from
engaging the PTT on SSB and saying "Kilo Three Kilo Oscar?"

I realise we are drifting off the topic of ACOM amplifiers here,
but I fail to see the huge advantage of full QSK as some are
advocating. I accept that with modern gear it probably doesn't
shorten equipment life much, but I'm getting the sense it is more of
a personal preference, like using a foot switch as opposed to a PTT
on a mic, or using VOX instead of a any switch activated PTT. Is it
really that much better? I just tried working the S04R on 17
(without success because he is 419 with deep QSB) with and without
full QSK, and I really can't see the advantage other than QSK is distracting.

My understanding of QSK was that it originated in the commercial/military areas when it was sometimes necessary to break in with emergency traffic. I don't think it has a significant advantage in DXing or contesting. At least it would not help me.

73, Paul VE1DX

3087. Re: 2000A - relay alarm

Yahoo group: acom-list (1999 — 2009)

Topic: 3066 Message: 3087

I had to replace the Kilovac HC-1 relay in my 2000A very shortly after purchasing the amp new. It was a relatively early 2000A, built circa 2001.

I was told by Acom that they had received a bad batch of Kilovac relays. I happened to have a Jennings RJ-1A on hand, so I used that as a replacement and it's still in the amp today and functioning just fine. Acom sent me a Russian relay, which is on standby in my parts box in case the Jennings relay fails.

Anecdotal evidence suggests the problem had nothing to do with a bad batch or relays. Others have replaced the Kilovac relay with a Jennings relay and have had the latter fail. I am almost certain that I was using QSK when the original Kilovac relay failed (I was using the recommended keying loop with a Yaesu HF rig that supports TX ENA.) The amp was new enough that there's no way the relay wore out. I had used the amp in perhaps one contest, and only for S&P on the second radio, no running. I have rarely used QSK since, out of fear that the relay will fail again. The amp is still on the second radio, so it gets relatively light duty. So far, no problems.

Note that prior to obtaining the 2000A, I used an Amp International LK-550ZC, which has the same type of vacuum relay. No problems with the relay, even after years of pounding in QSK mode. Same for an SB-220 amp I retrofitted with a Jennings relay before that. I wouldn't expect a vacuum relay to last forever under heavy repeated QSK contest operation (with repeated CQing, it doesn't take long to get up to the specified maximum number of cycles, which is something like one million.) However, I would expect it to last more than a couple of years.

Personally, I think there's a timing bug in the 2000A firmware or hardware that leads to hot switching of the relay. Stan has insisted that this can't possibly happen due to various safeguards, but the fact that a large percentage of Acom users has had to replace the relay says otherwise.

>
> a) Do not force or stress the relay leads during unsoldering and soldering. Use a solder vacuum pump during unsoldering to remove all the solder before taking off wires from the relay leads.
>
> b) For contact leads use a powerful soldering iron of 100-150W, with a massive copper tip, since the relay leads and ceramic draw much heat. The soldering tip temperature must be between 280 and 350 degs.C (535-660F). The soldering time must not last longer than 4-5 seconds after the solder has melt, and must be less than 10 seconds totally. Otherwise you risk overheating the meatal-to-ceramic vacuum-proof joint and destroy the relay. Wait minimum one minute after each soldering to let the relay case to become cool. The resulting joint must be lustre and without sharp tips. Use only non-corrosive flux. You could use the old relay to try soldering method on it before doing on the new one.
>
> Clean the ceramic surface with alcohol but not before it becomes cool.
>
> c) For coil relay leads a small soldering iron would be suitable. Nevertheless, be very careful because the plastic coil frame is fragile and could be easily broken. The problem arises while one tightens the nut, if the tool would slip suddenly. Anyway, they offer spare coils for Jennings and Kilovac. The Russian pins are much stronger.
>
> d) When tightening the relay nut, the maximum permissible torque is 10N.m (about 86 Lbs.inch). When you have no dynamometric wrench available, please note and remember how do you feel the force you have used while loosening the old relay. Use a similar force for the new one.
>
> e) The contacts layout of the Russian relay is as follows:
>
> - Orient the relay with the contact leads towards you. Rotate it with the lead which is differently shaped to the bottom (it seems like a soldering lug and is labelled with "3" on the ceramic surface). This is the normally closed (N.C.) and it corresponds to the KILOVAC "A3". Connect it to the central wire of a neat coaxial cable, connected via a BNC connector to the tube deck. This is the RX- and STBY- RF bypassing path.
>
> - The upper-left is the common (COM) and is labelled with the Cyrilic/Greek Pi (it seems like inverted U). It corresponds to the KILOVAC "A2". Connect it to the central wire of the current transformer (located just below the relay).
>

As a matter of "good operating practice," I would monitor the post-amp RF envelope with a scope to ensure that the amp isn't being hot-switched. As Dick points out, there may be some operating combination that produces a slight timing error. The only way to really know is to monitor the post-amp RF envelope.

The Kilovac, Jennings, and Gigavac vacuum relays should normally be able to withstand many on/off operations. The Jennings relay in my nearly 40-year-old Alpha 70V s still standing up to my daily QSK abuse. Likewise, the Jennings RJ1A in my Alpha 77Dx has been similarly abused since the mid-'80s. Both amps are on their original vacuum relays. Granted, I may be running on borrowed time. But, until I added the scope to full-time operation back in '97, I found that my Ten Tec Omni Six was hot-switching the Alpha 70V and causing on-air key clicks. It went on that way for a couple months until I was listening to my CW signal on a standby receiver and heard the clicks. I was horrified to see what was being transmitted when the scope was connected. A revised QSK sample point inside the Omni fixed the problem.

Incidentally, if anyone is using an Omni Six with their ACOM 2000A -- and you're not hand-shaking with the amp in a loop, I would strongly advise against using the scheme advocated on the AlphaPower website where they use an RCA "Y" adapter on the Omni's QSK loop, together with a 1N914 steering diode. That combination will almost guarantee a condition where the amp will be forced into hot-switching. Whether the ACOM will take that into account under all operating conditions is another matter. And even if hot-switching is not occurring, the post-amp RF envelope time will not match the keyed RF envelope time of the rig. The so-called "dit shortening" is also possible as a result of timing errors between the rig and amp.

Paul, W9AC

Topic: 3066 Message: 3089

Hi Bob et al,

I guess the main reason I use CW QSK is because I have been
using it for the past 30 years and I am so accustomed to it that I find
it hard to do without it.
Also, I do fall into Brian's (K3KO) Group 2. I find it easier to keep in
"sync" while
calling DX stations, etc...
For SSB I use a foot switch. I find it much faster and more reliable
than VOX.

My rig is a Yaesu FT1000MP MK-V Field driving the 2000A.
I have both TX-IN and TX-OUT connected to the 2000A so I have
no hot switching issues...
I have become so used to changing out the vacuum relay that I don't mind
it a bit...

As Dick (WC1M) said, Stan of Acom indicates that there are various
safeguards
in the amp for this issue. However, I think the safeguards are too
sensitive to
very small variations in relay performance. I believe that the relays
that cause
these faults in the 2000A would work just fine in any other amplifier!!!!
My own opinion....

73,
Ted K2QMF

Sorry for late reply but was abroad last days. Indeed the PTT line was closed all the time during warming up and probably also during the self-tests. I use the FT2000 here and power off/on did "reset" the PTT and all back to normal.
Reading all the other posts here regarding a vacuum-relay failure makes me also wonder if the relay is damaged or is it just the sensitive protection circuitry? Anyone tried the bad vacum-relay after removing it from the Acom if it is still functional? and what is wrong with it; contacts burned out or?

3091. Reflected Pwr

Yahoo group: acom-list (1999 — 2009)
Date: 2009-04-16 17:53:29 UTC
From: Dave McLaughlin
Topic: 3091 Message: 3091

I'm using the A1000 into a G5RV antenna for 40 & 80. I can get full power on 40, but when loading on 80 I get the Reflected Pwr message and the amp shuts down even with 10 watts drive. My tunner (Palstar AT2K) says I have 1:1 swr. Anyone else ever experienced this? If so, what did you do to cure it.

Thanks, Dave

3092. Re: [acom-list] Reflected Pwr

Dave:

Do you have a dummy load? If so, take the tuner out of the line and use the dummy load connected directly to the amp and see if you still get the error message.

Also substitute a different coax cable between the amp and tuner and see if that makes a difference.

I doubt the problem is in the amp, but you never know.

Frank,
Thank you for your reply. I don't have a dummy load but, I did try using the tuner in direct mode and with about 4:1 vswr, the amp worked ok up to about 500w. Anything higher than that I receive the same error message. I did change out the coax, but got the same results.

What coil I have to select for HC-1 replacement by GH1 ?
I assume 48Vdc, but not sure.
Please, confirm or correct me.

Thanks in advance.

Als het goed is heb je 2 jaar gearantie, je kunt vragen of je het relais zelf mag vervangen, je moet het oude dan opsturen.

Hi Thomas,

recently I had a fault of the output relay in my Alpha 91b. I sent an email to Gigavac and they gave me a ham GH1 relay which was 26,5V version, but they did not even ask for coil voltage. I just fit the relay in the amp and it works. I suppose all relays in the ham amps are the same.

You can also check the voltage on the relay with voltmeter, but be careful the HV in close.

Here is the link:
http://www.gigavac.com/products/relays/datasheets/gh1_ham/index.htm

Judging from the schematics ("interface" board) in the file section you need a 26,5 V relay.

48V is applied to the relay, but trough a 330 ohm resistor. This resistance is the same as the coil resistance of the 26,5 V type, so steady-state the coil will have about the half of 48 V of it.

The 48V is used to generate a switching pulse for the relay by the use of a by-pass capacitor across the 330 ohm resistor. This is likely done to speed-up the switching time, but might also be the reason for the limited lifespan of this relay.

Hi Guys,

I have a question, when I work with my ACOM1000 a tempo is 70/75° is normal temp?

Best 73!

Sincerely and 73,

FIRMA-FRANK1

Thomas,

The Gigavac relay you need is the GH1 HAM with the 26.5 Volt DC coil...

3107. RE: [acom-list] Re: Acom 1000 failure => ACOM2000

Yahoo group: acom-list (1999 — 2009)
Date: 2009-04-23 20:38:48 UTC
From: Kees - pa7two
Topic: 3100 Message: 3107

Hi Uffe,

This wrote Stan to me when I asked why normal relays are used in the Acom 1010 and not the GH-1 or equivalent:

The coil supply voltage is
12V DC while vacuum relays are typically 26.5V DC (although 12V types can be found). The problem is aggravated by the fact, that for QSK a vacuum relay should be powered with at least 1.5 times higher voltage and a R-C pair to speed it up (as it is done in ACOM2000A and ACOM1000).

So, your statement should be correct :-)

Vy 73, de Kees.

Statement of the year: THE HECK WITH YOUR MICROPHONE, I'M PAWING BRASS!

To: acom-list@yahoogroups.com
From: pa5dd@...
Date: Thu, 23 Apr 2009 09:39:46 +0000
Subject: [acom-list] Re: Acom 1000 failure => ACOM2000

Judging from the schematics ("interface" board) in the file section you need a 26,5 V relay.

48V is applied to the relay, but trough a 330 ohm resistor. This resistance is the same as the coil resistance of the 26,5 V type, so steady-state the coil will have about the half of 48 V of it.

The 48V is used to generate a switching pulse for the relay by the use of a by-pass capacitor across the 330 ohm resistor. This is likely done to speed-up the switching time, but might also be the reason for the limited lifespan of this relay.

Thanks both Kees'ses for the reply. I purchased my Acom more then 2 years ago so no warranty anymore.
I don't use full break-in only semi break-in. Question for PA5CW: did you had to replace the vacuum-relay right after the error message or did this message showed up a couple of times before you had to replace it? Since the error message I did not saw it again and the AMP is working like normal. The reason for this question is did the relais fails/stucks immidiatly or did you get some " pre-warnings" first. With pre-warning I mean the TR4B error. If the vacuum-relay already fails after 2 years then I think it's a really weak point in the design. I'm not using the ACOM daily and with periods not even weekly. Semi-breakin is maybe used average one hour per month in total, maybe even less.
I don't like the rattling sound of the relais when using full breakin and I'm also convinced that this may contribute to a broken relais earlier then when you only use the semi-breakin.

Thanks for the replies, best 73's Ger PE1CZG

From: Andrey Stoev
Topic: 3100 Message: 3112

As a side note - If I was about to change the vacuum relay I'd go with Kilovac relay (like Kilovac HC-1 (exact replacement for GH-1) or even better HC-3) instead of Gigavac relay. Kilovac relays are a bit more expensive (totally worth) but are far better and more reliable then the Ham version (GH-1) of Gigavac. Gigavac relays are generally made in China btw. Relay replacement is a chore so IMHO one should put in the better relay if can be found for reasonable price!.

3113. Re: Acom 1000 failure

Yahoo group: acom-list (1999 — 2009)
Date: 2009-04-24 00:14:09 UTC
From: Andrey Stoev
Topic: 3059 Message: 3113

I posted on the subject a couple of hours ago but seems that the post was lost (sorry if it shows up and "doubles").
In the early production life of ACOM 1000, they used to use Russian vacuum relays. As with most Russian stuff - they were very rugged and pretty good but without consistency in the quality control - i.e. some were very good (my amp has one of those) and some were junk and broke down soon after. There wasn't good way to tell - just time and usage. Anyway - since the supply of the Russian relays is not reliable ACOM changed the relay.
The newer amps are equipped with Gigavac GH-1. These relays are OK but are made in China so more or less - same thing applies (overall better than the average Russian relay). Of course use of full break-in will shorten the life / expose problems with the quality of the relay.
If I had to change the relay, I would use Kilovac HC-1 (or even better HC-3). Kilovac relays are a bit more expensive but far better and more reliable than the Ham version from Gigavac (GH-1). Installing the relay is not a small job so if you find a Kilovac/Tyco relay for a reasonable price - go ahead and install the Kilovac relay.

>
> Thanks both Kees'ses for the reply. I purchased my Acom more then 2 years ago so no warranty anymore.
> I don't use full break-in only semi break-in. Question for PA5CW: did you had to replace the vacuum-relay right after the error message or did this message showed up a couple of times before you had to replace it? Since the error message I did not saw it again and the AMP is working like normal. The reason for this question is did the relais fails/stucks immidiatly or did you get some " pre-warnings" first. With pre-warning I mean the TR4B error. If the vacuum-relay already fails after 2 years then I think it's a really weak point in the design. I'm not using the ACOM daily and with periods not even weekly. Semi-breakin is maybe used average one hour per month in total, maybe even less.
> I don't like the rattling sound of the relais when using full breakin and I'm also convinced that this may contribute to a broken relais earlier then when you only use the semi-breakin.

hi,
in my case the error message appeared rather seldom at the beginning. Later on it appaered from time to time and time slots became shorter and shorter. Before the brake down the failure came up several times during a hour and finally suck.

By the way: thanks for all replays regarding the coil selection. I learnd a lot and allready ordered a new relay for replacement.

That sounds normal, Frank. When my ACOM 1000 is idling, it is between 38-42 C, and during a prolonged transmission it gets to about 80 C, but cools off quickly (1-2 minutes or less). The fan is variable speed and as the temperature increases, so does the cooling airflow. Yours sounds like it is working fine to me.

The best thing to do to ensure long tube life is to keep the air intake filter at the rear clean. I vacuum mine about one a month to clean out any dust, etc.

My two cents on the question raised:

Running relative low RF output is not that good with regards the temperature. My amps loafs on about 700-800 watts output at around 70-80 degrees celcius, the same sort of temperature applies when running lower power like 400 watts!

400 watts being the legal limit in PA land... :-(

Thomas,

Thanks for the info. Can you tell me where you did order the relay and what the price was/is? I'm going to order a replacement as well but found sources in the USA sofar.

Thanks and best 73's Ger PE1CZG

Hello Ger,
I had to order the relay GH1-HAM at GigaVac direct ; the european dealer (HVC Technologie GmbH) has no access onto (cheeper) HAM-version relays. They gave my order to GigaVac and they offered for 77,- US$ (VISA accepted).
If the relay is delivered I will keep You informed about additional costs, if so.
73 de Thomas, DL1AMQ.

Thanks Thomas for keeping me updated, 77$ is not a bad deal.
I want to order the GH1 myself and of course interested in your expirience. Hope it's not to complicated to exchange the vacuum-relay.

I've uploaded instructions for Vacuum Relay replacement in ACOM 1000, along with some pictures of the relay assembly and pinout.
All files are located in group's Files section in VacRel_A1000 folder.
These files are courtesy of ACOM.
Enjoy!

Great service, Andrey.
Is the same info available for Acom2000 also ?

I got the ordered GigaVac vacuum relay GH1 today; very fast delivery.
In addition I had to pay 31 ☐ for incoming tax. But I'm happy to have the spare part available for replacement.
73 de Thomas, DL1AMQ.

3124. Kilovac 1 vacuum relay source

Yahoo group: acom-list (1999 — 2009)
Date: 2009-04-29 22:00:16 UTC
From: pe1czg
Topic: 3124 Message: 3124

I ordered a new Kilovac HC-1 here in the Netherlands:
http://www.elektrodump.nl/ then go to Schakelaars / relays -> HF + HV + Coaxial relays

Cost per relay: 18,50 Euro brand new.

73's Ger PE1CZG

3125. Acom 1000 Problem

From: vprez100
Topic: 3125 Message: 3125

I have an Acom 1000 which is over 2 years old it had a fault develop on the 24vp supply C5 had to be replaced It had gone faulty, My amp now works OK however has a strange fault when I first switch it on the temperature reads - 14c or 3f which does increase as I use the amp after use it goes up to 0c or 28f so is working however seems to need calibrating
can any one please help or have any ideas I feel that may be there is a factory reset like the one on the 2000.
But can find no reference anywhere to calibration or reset.

Dear all,

Please be aware of the following:

Two hours after my message all the 2007 tubes are sold out... There were only a small amount available.

However, GU74B tubes year 2002 and 1989-1992 are still available, also in low quantities. Pairs (not matched) from same productions runs are available too.

Kees,

Wat is de vergoeding voor zo,n tube?
Kan ie zo gebruikt worden in een Acom 1000 met volledige specs?

Mvrgr,

Leo

-----Oorspronkelijk bericht-----

Onderwerp: [acom-list] NOS GU74B 02-2007 available FS

Hi all,

Now available in limited quantities: Svetlana GU74B tubes, manufactured in 02-2007 (No, it is not a typo, production year 2007!!)

Photos, pricing etc available on request via e-mail.

In case you need my e-mail address, use www.qrz.com for the lookup < pa7two > (or just use at hotmail dot com)

Vy 73, de Kees.

I think it's unfair to promote GU74B tubes for the Acom 2000A if the tubes are not matched. The tubes must be matched and there are still dealers out there that sell and completely test matched pairs. I don't think people want to get a set that might work and certainly not being matched.

In addition, it would be a big surprise to find out the GU74B tubes came from a batch from the year 2007.

My personal experience suggests that matching is really not that critical. I've tested 6 tubes purchased individually and had no issues pairing them up randomly in the 2000A, based on Acom's matching standard.

For one thing, Svetlana never made GU74b tubes. The GU74b designation is the former Soviet Union's term of their most commonly used MILITARY tube. It is dull looking, has Cyrillic writing on it, and they were made in large quantities in state sponsored factories in the East Bloc prior to 1991. Svetlana made a COMERCIAL 4CX800A tube that was electrically equivalent to the MILITARY GU74b tube used by the Soviet Union. They are not the same things. The 4CX800A is polished, and has Svetlana and 4CX800A written on it. It looks very much like an EIMAC 8877, etc. I know, because I have had both a GU74b and a Svetlana 4CX800A in my hands and examined them carefully. They are not the same. They might both work in ACOM amps, but they are very different looking tubes originating from very different factories, and they were designed with different uses in mind.

Every month or so this same argument comes up on this list. In my view, and I am not a list moderator so I have no authority here, this forum should not be the venue to buy and sell these tubes. There are far too many misconceptions flying around, false information everywhere on the Internet, etc. All of us have our own ways of finding spares and of deciding if the story of the day is right. The best thing to do is to talk to ACOM or other vendors of Ham radio equipment who sell these tubes.

This is a good forum for the exchange of information on ACOM amps, how to diagnose problems, etc. I don't feel it serves anyone's purpose if we use it to sell NOS tubes and turn this into a Swap Shop. There are plenty of them on eBay if we don't trust or can't find regular vendors who sell tubes.

Topic: 3128 Message: 3135

Why would matching be so critical? Over the past couple of years I have bought 8 GU-74B's on eBay. Tried them all out in my 2000A. They all work fine. What I did do was put them in pairs by temperature so they both would get up to similar temperatures at high power with key down for a while. When I lost my first tube I replaced it with a NOS. The temperature was around 10 degrees difference at high power between the original and "new" tube. But similar power out as before and did not notice anything weird or not running correctly.

Am I missing something about tube matching in this amp?

Assume that your response was to my posting. It was my intention to provide info on the matched pair situation.

I have never sold anything on the reflector and agree with you as it's not the place to promote tube sales. I have seen and spoke to people that got taken in when they heard a GU74B was up for grabs.

An interesting aspect in this discussion:

Try to order a GU-74B from ACOM.

They do not sell them.......Period!

ACOM has in a mail from their Technical Dept., dated May 5th 2008 (1 year ago today!) - listed 7-8 places to get hold of replacement tubes,
and also mention Kees PA7TWO sells good tubes.

The mail is signed by Stan LZ1IU.

When checking out the suppliers on the list - Kees was 1 of 2 who answered on an email request.

ACOM users shoud be very happy that they have people like Kees - who probably spend quite a lot of time and effort to find sources for this kind of tubes.

And a mail now and then - on this list to tell that tubes is available - for me that is not a problem at all - that is just valuable informations for
owners of ACOM PA's,

Could be, but all the advertisements of Kees for his tubes in this
Acom-group begin to look as SPAM and I receive more than enough of them
daily...

A few months ago someone else in the Acom-group asked Kees to stop with
his tube-SPAM, but Kees does not want to stop.

When I sell something of my radiohobby I use sites like
http://www.eham.net/classifieds/ (or hundreds others like this one) and
not a group like our Acom-group.

Topic: 3128 Message: 3140

I fully agree to what LA8AW says here !
I got the same written response from Acom Bulgaria when I tried to order new tubes for our clubs 2000A. In addition I tried to contact Svetlana. After some time I got a response telling me they did not make any GU74B or 4CX800 tubes, and the lady that contacted me did not know if such plans existed at the present time.
Acom in USA did for some reason not even answer my emails...might have been a case of lost mails though....
Kees PA7TWO sent us some very good tubes...they match to within 2 degrees centigrade at full power after adjusting per Acoms instructions ! And Kees never even claimed they were matched ! :-)
The tubes have now performed excellent in many 48 hour contests. Thank you to Kees for his excellent
service !
These tubes are not, and I repeat NOT available as a standard stock item anywhere !
Some dealers (only one that I know of....) offer them NOS and tested/matched...but it is always a question of availability !
The are scarce,- and will be ever more so as time goes by, Keep up your service Kees !
Peter

3142. Matched tubes

Yahoo group: acom-list (1999 — 2009)
Date: 2009-05-06 09:42:47 UTC
From: Hal Kennedy
Topic: 3142 Message: 3142

I almost posted a long technical discussion yesterday on why matching is unnecessary but held back. Now that the claim has been made that matched tubes are necessary - I would like to learn why. Will anyone who believes a 2000A needs a matched set provide a TECHNICAL BASED defense of their belief?

I appreciate Kees' offers of tubes for sale. At times the tubes are hard to find, and at times its easy to get bad ones on eBay - Kees sells only good ones when he can get some - a service to us all. They aren't matched and trust me, they don't need to be.

I am not an Electrical Engineer and I have an single tube ACOM-1000, so I can't provide you with a technical explanation on my own. However, the issue of matched tubes in multi-tube amps as come up since I've been licensed, and a person who WAS qualified put it to me this way:

"Think of the tubes as 2 resistors in parallel. Assume they are 100 ohm resistors and you apply 1000 volts across all of them. If one is really 110 ohms and the other is 90 ohms, the one that is 90 ohms will carry 20% more current than the one that is 110 ohms. Hence the tubes will be doing unequal amounts of 'work' and it just makes sense to have them bothl the same, whether they both be 110 or both 90." He went on to say that in the old days, suppliers didn't measure anything in the tube itself. They just stuck pairs in (like 811As, 572Bs, 3-500Zs, etc) until they got two that had close to the same plate current and called them a matched set.

I always thought of it in these simplistic terms. If there is more to it than that, please elucidate.

I'm interested in finding out if my simple explanation of why tubes should be matched is right. I don't think there is an easy way to measure the resistance/impedance of these things outside the amp. It is further my guess those who are claim matched sets are using temperature as indirect, anecdotical evidence that the tubes are carrying the same load. This makes sense because they would be

dissipating the same amount of power when matched and should have about the same temperature in the exhaust air if the tubes are "matched." Am I correct?

73, Paul VE1DX

I, too, am not technically qualified to offer any technical reason as to why the tubes in the 2000A must be matched. But I believe VE1DX's explanation does have some merit. From the Acom OPERATING MANUAL it states the following;

"6-4. Tubes Replacement
The new tubes must be supplied as a Matched Pair with close electrical characteristics. Otherwise one
of the tubes will bear an excessive share of the operating currents, which will lead to overheating and
reduced tube life."

Perhaps we should follow the manufacturers recommendation as closely as possible?

And in defense of Kees I would encourage him or anyone else who has a parts source for Acom's to continue to post the availability and sources for those parts.

Here is my personal experience on the matched tube matter:

My 2000A lost one tube and just prior to the failure; the tube which went out started to operate at a much higher temperature range vs. the other one. The two were always within a few degrees of each other and then suddenly there was about a 12 to 15 degree differential.

Krassy dropped over to my place one weekend with a box of new tubes and he installed several pairs until he found two that met certain parameters in the set up, and don't ask me to tell you what they were, because I don't recall. However he was very careful to pick out two that were "matched" based on the parameters of the amp. He then aligned the amp and that was it. After the new set was in and aligned, I notice the two tubes were running at almost identical temperatures and still do. They were even better then the two that came with amp when purchased new.

I agree with the analogy on the parallel resistors. A mismatched tube will draw more current and hence run hotter which should cause it to sustain more stress than the other tube. But that is just my opinion. I am not an electrical guy, I am a physics guy, so what do I know? My old 30L-1 running 4 811A's always was an issue trying to find 4 that glowed the same on the plates. The ones which were glowing hotter always melted through prematurely and as such I used to swap tubes around until I found 4 with equal heating. When I did that, they lasted much longer than the random sets with certain tubes pulling more current.

The factory (i.e., Stan) defines a match as a difference of 8 degrees
or less in exhaust air temperatures of the two tubes. This is easily
accomplished.

Some folks are going to feel safer purchasing "matched" pairs and
others of us are confident in fending for ourselves.

Hi

I am a bit confused about this tube thing.

I'll get my new A1000 in 2 weeks time or so and if all stories are true these tubes will run out soon. I feel a bit hoaxed :)

I just can't figure out why Acom is still making amps with these gu74b tubes - shouldn't they have been replaced it with an other one? There must a hidden source for those but still I need to get few for a spare for sure.

There must be lots of different amps (pros too) out there using these tubes so I belive it wouldn't be a bad idea for a tube company starting to make these again. :)

There are plenty available in small quantities in Europe. Check Ebay, pick you up a spare and you will be set for a long long time.. The rumors fly about them not being available but that is not true.. A friend of mine just purchased a pair several days ago, they work just fine as he has checked them out in his Alpha amp.

Don't get led into the panic. Your new amp may NEVER need a spare tube, but spares are available, despite all the hysteria. If you're really nervous, buy another tube now, test it out, then put it (or the original) on the shelf and you will be set for life. Operate the amp within design/tune/operate limits and it will go forever.

The archives of this reflector are at
http://groups.yahoo.com/group/acom-list/
and you can do a search for the tube and find sources.

As you may have noticed, tube discussion on this reflector is rather controversial; the archives will tell you everything you need to know.

Don't worry about your new amp or Acom....both are high quality! Relax, and enjoy your new amp.

I have owned my acom 2000 6000 hrs lost low voltage PS and a Tube it was repaired under warranty I bought some tubes before everyone started hoarding them. about 100 each I bought 4 tubes do not get sucked in on the matching as much as heat range the best way is to run new tubes and check temps after a short time and swap them around these our very rugged tubes They will be around longer than both you and I as long as everyone doesn't drive the price up. There is a huge surplus on these tubes NOS our excellent buys and beats 500.00 or 700.00 bill for some of the newer still production . And since the factory would like the surplus to dry up there like our version 4cx1000a that were used in the old collins 30s1 you can buy them all day for 75.00 150.00 Remember you have 4 years on the amp and two years on the tubes . In the mean time watch ebay for a good buy on some NOS . And enjoy your amp you bought the best.

I decided to drop my 2 cents in the tube discussion after seeing this extensive thread...

GU-74b is MADE by Svetlana. It is printed so on the box and on the little paper booklet that goes with the tube! Svetlana's logo is printed on the box, booklet and the GU-74b tube as well! GU-74b is the original Soviet Era designation. Most russian power tubes are using this "GU" prefix!
GU-74b was initialy designed for MIL purposes and manufactured in large numbers by Svetlana.
Once the tube became popular for use in amateur amplifiers (Acom is just one mfr, Alpha - another, etc), the russians introduced "4CX800A" name to make the tube look like an EIMAC tube. They just wanted to make the tube more "consumer friendly /commercial" and wanted a familiar to westerners name type. In their mind this was a step needed to boost the sales! That's all! For this very same reason the tubes manufactured as "4CX800A" are polished and shiny - people in the western world are not used to the crude look, very common for soviet military equipment and parts. (btw. the little rombic shape on the side of the tube is a stamp for aproved MIL use, (as a bit of trivia - two little rombs - for special equipment use (read "nuclear"), three rombs - spacecraft use)).
The tubes GU-74B and 4CX800A are IDENTICAL in every way except the look (polished vs unpolished plating and different print). Furthermore, I personally asked Stan (the principal designer of the ACOM amplifiers) on the subject and received exactly the same answer - both tubes are IDENTICAL and aproved for use in ACOM amplifiers. "4CX800A" tend to be newer tubes.

4CX800A are still manufactured (there was an interuption in the production of these tubes). GU-74b left over from Soviet times were available in large numbers and were inexpensive (one of the reasons for their popularity) but as the stock dried up, the price went up as well. Most of the russian dealers are trying to unload what's left from GU-74B stock pile before they start offering widely "4CX800A". A sign for this can be seen on eBay where the newer 4CX800A are being offered more often now.

As for Kees - offers like his can be seen in almost every group - he is not selling random parts but something essential for our amplifiers - something that wears out and people are in a need for every now and then. It is a good thing to have a choise where to buy it.

ACOM Bulgaria also sells these tube (at least last year they did) but the their price is rather high!

ACOM USA will send you to buy it from QRO-Parts.com if you ask for replacement tube.

I've had my ACOM1000 for around 4 year's now and the tube is starting to go down.
I do a lot of FM work and i dont think it like's it.
When it was new i used to run around 26 Watts input to get 480 Watt's output.
Now i have to run around 40 Watt's into it to get 450 Watt's out and i have to run around 90-100 Watt's to get 1050 Watt's out of it.

So i think it is what you are going to use the amp for, as to wheather you get worried about spare valve's.
I think i've got around another 2 year's before it finally give's out and then i will be panicing about where i get a tube from.

New stuff from ACOM at the Dayton Hamvention

Digital watt-meter using VFD display - looks really neat. One interesting feature is an USB port on the directional coupler along with the Display Unit port. I guess you can use only the directional coupler + computer. The meter itself looks very well designed and of a high quality! The meter unit is small with buttons for PEAK, AVERAGE, MENU, etc. I didnt see the meter in action - I was told by the Array Solutions guy, that he *thinks* the unit they got is a non-functional dummy unit just so they can introduce the new product! Got some pictures which I will post. No pricing info was avilable. I have also the spec sheet for the meter which I will try to post as well.

The other news is about the ACOM 1010 amplifier. There is a new version of the amplifier using 2 x 4CX250B tubes instead of the single 4CX800A/GU-74b. There was no technical data sheet with the new unit. Everything else looked the same. I have some pictures which I will post in the Photos section in the next day or so.

This doesn't seem to make sense,

Why use 2 tubes with only 500 Watt Plate dissipation Total
when original tube has 800 Watt dissipation ???

Actually, according to the spec sheet, the 1010 is rated for 700W PEP and 500W cont. carrier. They are probably pushing the tubes a little over their factory rated power which should not be a big deal. They are doing the same thing with ACOM 1000 - 4CX800A/GU-74b is listed as 800W dissipation but ACOM 1000 delivers over 1000W with no problems!
I guess it is a cost saving measure but the end-user also benefits from it - when it is time for tube replacement you'll be able to buy less expensive tubes (I saw at Dayton's flea market this year 4CX250b (NOS) for $25) The only bad thing is that China also makes 4CX250B. I couldn't tell if the ones installed in the sample were chinese because of the silicon chimneys.

3162. How to open A1000 cabinet?

Yahoo group: acom-list (1999 — 2009)
Date: 2009-05-19 14:50:09 UTC
From: John K Gotwals
Topic: 3162 Message: 3162

A few months ago, following a suggestion on this forum, I set about cleaning the air filter on the back of the unit. After removing the two bottom screws from the filter shroud, I decided the noise I was hearing was the sound of nuts dropping on the inside of the amplifier. I am now in the process of changing my QTH, and have decided it might be a good idea to open up the amplifier and locate and remove the two dropped nuts. If possible, I will reattach the nuts to their respective filter shroud screws, but it may be difficult to access that portion of the amplifier without a very major disassembly.

What are the steps one goes through to open up the amplifier cabinet? I have noticed that there are three nuts on each side of the amplifier case and three nuts on the back top of the case. I am guessing by removing these nine nuts I should be able to slide off the case.

Advice and suggestions are greatly appreciated.

Hello,

I am just wondering, what's wrong with
4CX250B's made in China???

Thanks for the info...

73,
Ted K2QMF

That's pretty much it! Remove the screws and the cover comes right off.
The only problem that you'll have is to re-attach the filter's bottom right screw (looking at the back of the amp) - actually the nut on the inside. This nut is in a very tight space. You could remove the power transformer to get access but it is a much biger job. If you can't put the nut back on, just leave it off, (of course remove the nut from the cabinet).
When I was installing my AUX fan, I was able to hold the nut in place reaching from outside, between the blades of the fan, but in your case you are putting the filter back on so you'll need to find a way to do it from the inside of the amp. Magnetic screwdriver or wrench might help, or just use a little PVC tape to attach the nut to the tool you are using so you can place it against the hole and once the screw is in, remove the tool and the tape. Than you have to find a way to block the nut from rotating while tightening the screw on the outside.
You can also try to revert places if you having trouble installing the nut - put the screw from inside and the nut on the outside.
The bottom left nut is really easy to install.

Hope this helps!

I had a similar experience. With the help of ham friend, a pair of good Kelly clamps we were able to replace the nuts on the back again. I was not able to put the lock washers on one of the screws, but see no problem. You can reach the area once you have taken the cover off. Lesson learned, especially as I found out there was no need to remove the cover screen in the first place.

NP! If one wants a 1010 with GU-74b, I guess now is the time to buy it before the old stock is gone and the new 1010 with 2 x 4CX250b hit the dealerships...
(If I had to make this decision I would probably go for the GU-74b version)

Well, it is probably just me! :) As somebody pointed out, I rather have a single valve which is conservatively rated at 800W than 2 smaller 250W valves that require "matching" and are pushed beyond the rated power! I'm sure the new model will deliver the power in the spec sheet - maybe there is no good reason for it, but here is another one - I am more comfortable with Russian mil valves pushed beyond their specs than with those made in China.
The GU-74b lasts really long time so for me the tube price is not a big concern but I understand that other people prefer to have amplifier using less expensive valves. Most probably when the top cover is on, both versions will be indistinguishable - just right now those planing to buy 1010 have a choice when it comes to the hardware.

For the new users and the experienced users....
When was the last time you cleaned the filter?

To keep the amp happy you should clean its filter at least every three months unless you're in a dusty environment.

Here in AZ I wash the filter every two months.

I have had my 2000A now almost 9 years! It has required some service over that time. A low voltage power supply failure during its first year, a low bias challenge twice but Acom did an excellent job and the amp is "perfect"

I use it with a Sommer XP707 log beam and an Icom 7700.

What is the best way to remove (for cleaning) the two outlet filters on top and the inlet filter into the fan on the back? The manual says "DO NOT OPEN" for cleaning.

I am in a low dirt/dust environment but it might be a good idea. There appear to be plenty of airflow from both tubes.

John,

The "input" filter on the back of the amp is the one you need to clean periodically.

The tube outlets should be clear and not need cleaning.

To prevent dust from settling down into the tubes, you may want to place a small, single sheet of paper over the tube vents when you are not using the amp. If you forget to remove it, the air flow should force the paper up & off and get your attention as it flops around on top of the amp.

Bob,

I took the suggestion of a sheet of Kleenex taped to the side of the output airflow and it works great. When not in use it simply folds down over tube openings and when amp comes on it elevates to allow airflow. The rest of the top does have a lot of dust so real happy about this simple mod.

Steve
K1IIG

John,

The "input" filter on the back of the amp is the one you need to clean periodically.

When was the last time you cleaned the filter?

To keep the amp happy you should clean its filter at least every three months unless you're in a dusty environment.

Here in AZ I wash the filter every two months.

I have had my 2000A now almost 9 years! It has required some service over that time. A low voltage power supply failure during its first year, a low bias challenge twice but Acom did an excellent job and the amp is "perfect"

I use it with a Sommer XP707 log beam and an Icom 7700.

From: paul glassman
Topic: 3177 Message: 3177

I have a spectacular "like new" Acom 2000A
and 3 extra sets of nos finals. I will trade for an icom 7800 or sell
the amp outright. 7800 age does not matter as long as it has the third
roofing filter and the upgrades are current as of june 2009. must be
from non smoking and have full factory box set.

Can anyone tell me what the rating is for the PTT line......??
Would i be able to use a Heil FS-2 foot switch with it....??
It say's it has a 10Amp relay in the foot switch, but i dont know how much the Acom draw's.
I'm thinking of getting another Icom radio, but i have never had much luck with Icom and my Acom1000, for some reason i alway's get HOT SWITCHING with Icom radio's, so thought i might get a Heil FS-2 to swicth the Acom.

Thank's.

Chris

The Acom 1000 ptt line draws only around 10mA, so your footswitch is well and truly man-enough.

You may still get hot switching errors, unless you can guarantee to hit the footswitch just before the mic button every time. Sorry I don't have any Icon rigs here so can't help further.

What Icom radio are we talking about?

Many older Icom (Pre- 756 Pro3) radios have initial keying spikes that exceed the input rating of the Acom amplifier.

If you have one of these radios, you will likely have problems.

Hi....

Thank's for the reply's.

The heil FS-2 footswitch has 2 switch's in it.
One for the mic PTT and one for external equipment, such as a linear Amp.
The external one make's contact before the PTT one, so should stop the hot switching.

The PRO3 was the only Icom i have had that never hot switched and i tried a 751,775,746 and a 706(which only hot switched now and then).

When i spoke to RON at VINE he told me, he had customer's who use the 775 and 746 without any problem's and it was something i was doing wrong and not a fault with the Amp, but i guess my Acom1000 just does not like Icom's.

Never had any prob's with Yaesu and had a few prob's with a Kenwood TS2000.

Chris,

It is very likely that the 751, 775 and the 706 has the initial spike problem. The 746 may also if it is an early unit. The 706 is probably the worst Icom for this problem.

It is not that the Acom does not like Icom radios; it is that the Icom radios have a problem that they put out a very high spike of RF output when you activate PTT.

Your footswitch will not change this problem at all.

Again, it is the radio that has a problem. It is not what you are doing, and it is not the amplifier.

Chris,

I had a similar problem of Hot Switching my Acom 1000 with my Icom 746 . Hot Switching. occurs when the RF from the radio reaches the amplifier before the amplifiers T/R switch has been fully switched to the T/R mode. The IC-746 send relay is too slow for the Acom 1000. The Acom's fault detection mode protects the amp from Hot Switching and you get the error. It is my understanding that the IC-746 also produces an RF pulse of about 4 milliseconds duration about 2 milliseconds after the PPT of the IC-746 is released. This is also sensed as Hot Switching by the Acom 1000 after release of the PTT (key up). This was documented in an email by Bob Garwood (W0BV) on the Acom reflector back in 2002. The solution is to use the faster HSEND keying output in either the ACC1 or ACC2 in addition to the Send RCA. I solved this problem by having an interface build that uses both the ACC2 and send (RCA) connections on the back of the radio. My notes show that the circuit was designed by Stan LZ1IU and worked for me on both my IC-746 and subsequent IC-756Pro. If you send my your email address I will send you a scan of the circuit.

Hello all,

Is it possible to connect 2 Acom amplifiers to a single IC7800 without a switch when i switch from HF to 6 metrs vice versa ?
I want to use the 2000 for HF and the 1000 for 6 meters.
Maybe an idea to use the Acc1 or 2 -port and the relay to use both amplifiers.
When you've experience with that or an idea .... i look forward to it !

Hans

From: kamarty456
Topic: 3189 Message: 3189

I would appreciate it if you can go into the parameters of your amplifier and read the line voltage value, and post it.

I recently noticed my 240VAC line voltage level was 250-253VAC.
According to the local power company, who sent out a technician immediately, told me +/-5% is typical, or 126/126=252VAC at the high end. The down side is the heater LED will flicker and the heater voltage is 13.3-13.5v when I have a 253VAC value.

We discussed my use of the 240VAC line and he even verified the transformer on the power pole is within tolerance.
When he made his measurements he read 248VAC and I had the exact value on my Acom 2000A. I believe the Acom values are accurate and the amplifier is fine. The 248VAC value is well within the tolerance range and the heater LED and voltage is fine.

We agreed the voltage variation may be due to demand loads when I'm on the air. I plan to monitor the 240VAC line for a while to determine if there is any trend. If there is a trend, the power company offered to provide a recording monitor to evaluate the service.

I must say I'm very lucky to have such a responsive power company. Then again, over the years I have established a reliable rapport with
them.

Thanks for your input.

Marty the 240 volt outlet where I plug my Acom 2000A into reads 239.6 VAC on my Fluke 77. The Acom control head Mains reads 238 volts.

My filament voltage reads 12.5V.

This is with the House Central Air running.

I also have a question for the users, I typically see only a 2 degree difference in the TEMP-R and TEMP-F when operating (Transmitting) the 2000A which is good but one station I talked to recently running a 2000A said he saw up to a 20 degree difference between the front and rear tube temperature which sounds way out of line. Sounds like he has a problem.

The specs for the GU73b say 12.6 volts for the filament. While these tubes are very rugged, I would be leery about exceeding this by very much. It's a case of "who do you believe, the Fluke or the ACOM?" To be on the safe side, were it me I'd verify that the filament voltage is not exceeding 12.6 volts, and as Hal says, having the 2000A calibrated would be a good idea.

I'm using an ACOM 1000, and I could find a way to measure the filament pins of the tube using a good voltmeter like a Fluke 97 or equivalent. It is dangerous to be taking these things apart unless you are sure you know what you are doing. I don't know anything about the 2000A other than it runs the same tube(s) and the specs should not be any different with respect to the filament voltage.

I'm not sure how one calibrates an ACOM-2000, but someone was selling one here recently and said that it had been returned to ACOM for alignment. My guess is alignment includes (or is another word for) calibration. This may be something that requires a return to the dealer. Better that than popping tube heaters prematurely.

Mains measure 242.5 on a RatShack DMM. The Acom says it seems 246 (delta 3.5V)!

This is using semi-rural power, provided by Kansas City Power & Light. 105+ heat index today, and everyone is runing the A/C full bore. Lots of variations noticeable on the mains.

From: Andrey Stoev
Topic: 3189 Message: 3194

Hi,

I've made a simple digital voltmeter to monitor my AC line - it cost me $20-$25 at the most! Here is the link :

http://blog.kotarak.net/search?updated-max=2009-02-04T15%3A34%3A00-05%3A00&max-results=10

This voltmeter allows you monitor also each half of the center-tapped power transformer bringing AC to the house (2x120V)
I have an Acom 1000 and it doesnt have the built-in AC line voltmeter.
Its not of a "True-RMS" type but it agrees within 1-2 volts with my calibrated benchtop Fluke.

3195. using a 240VSC variac?

Yahoo group: acom-list (1999 — 2009)
Date: 2009-06-30 19:12:55 UTC
From: kamarty456
Topic: 3195 Message: 3195

If you have read my recent posts regarding the high 240VAC line voltage I'm experiencing. I have another question....

I have closely monitored my 240VAC line at various times during the day. I also have not been able to determine and particular trend. The transformer on the power pole supplies my home and three other homes.

Observing the recent comments of my other post I notice most of you are seeing 235-242VAC.

I typically fluctuate from 242-254VAC. I am experiencing the heater voltage fluctuate from 12.6-13.5VAC and the yellow LED flashes. I also realize I'm still within the tube's parameters and perhaps I'm just over cautious.

I have found a 240VAC in [adjustable] 250VAC out rated at 5kvac [20amp] variac.

Should I consider this to ensure the supply voltage to the Acom 2000A is always around 240-245VAC?

Or should I not complain about being within the high range of the line Voltage supplied? SRP has told me +/-5% is within their range of normal, 228-252VAC -or- 114-126VAC per leg.

Contact your power company. They can make the adjustment at your pole transformer. They'll put a WESTON Volt meter at your input box with all your loads applied and make the correction.

I don't think a VARIAC can handle to power required for the ACOM.

My power company installed a larger POLE POT! Sounds like yours is on the wrong tap.

Same topic as you Martin, if I□m not on utility power, my large generator kicks out about 253 volts when in a no-load situation. The heater light flashes and goes out as soon as either we put the kettle on or start transmitting.

Should I worry myself or just leave it as is..?

Let me add an update to this topic....

Recently I purchased a small LCD AC voltmeter. It is a 3 digit panel mount style..when I hooked it up to my 240VAC outlet I read around 248VAC. The Acom 2000A amplifier on the "RCU" read 252VAC.

I used two other multimeters to verify the correct AC line voltage value and I'm beginning to wonder about what the Acom display is showing.

I now have the following questions:

1. Is there an adjustment to calibrate the 240VAC display?
2. Is there an adjustment to calibrate the heater voltages to the tubes? As I am seeing 13.1-13.5VDC depending upon the value of the line voltage.
3. The yellow heater lamp does flash quickly when the line voltage displayed is 252VAC or higher.
4. This anomaly has only started to occur within the past 3 months or so. My 2000A is almost 9 years old. I purchased it around September 2000.

-OR-

Am I simply overreacting to nothing and simply ignore it and enjoy the amplifier?

Marty,

"Mains" on my RCU reads about 7 volts high. I believe it has always been like this for the 8 years I have had the amp. Some time ago I looked at the schematics and it appears there is one ADC chip for most if not all analog readings with a calibration pot for it. There also appears to be separate adjustments for individual analog sources. My FIL-V also reads higher than I think it is suggesting perhaps a common adjustment. The amp will only pass about 150 watts or so before the alarm. I get away with it because the incoming voltage here is pretty steady around 240-243V and so far it has not aggravated me enough to take action. It is my opinion that a number of amps were not calibrated properly and that is what you are seeing. Misalignment in this direction should not hurt the amp but only aggravate the operator.

3200. 2 or 3 tranceivers on the same ACOM 2000 PTT RCA Connector

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-04 01:02:48 UTC
From: va2nrj
Topic: 3200 Message: 3200

Hello And thanks for reading me

What is the best way to connect 2 or even 3 transceivers on the same PTT RCA connector on my Acom 2000A

I know I can buy a special interface to control the PTT thru the microphone but I would rather use the PTT connector on the transceiver

I'm afraid to connect all the tranceiver in parallel !
I think the best solution is to build and use a homemade interface with optocoupler to 'isolate' each PTT transceiver connector

Any comments and/or suggestions would be appreciate

Robin

Robin,
It really depends on what rigs. If they have relays which ground the
PTT, they obviously can be connected in parallel.

If the rigs have "open collector outputs", they can be paralleled.

What I did to handle multiple rigs with different AMP KEY outputs was to
use a single ULN2003. It has 7 drivers (open collector outputs) in one
IC The inputs were conditioned so that the ULN2003's ground the ACOM
PTT line on xmit. The outputs from each driver was paralleled and
connected to the ACOM AMP key input.

To pull this off, you need to supply a + voltage to the ULN2003 input.
Some rigs supply this. Others may need an extra inverter stage (using
the same drivers in the package, to produce the + voltage.

Really quite simple. 1 IC with a couple of resistors (maybe) does it
all. It sure beats a bunch of opto couplers.

3202. ACOM 2000A Remote control

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-04 14:11:26 UTC
From: ik2typ
Topic: 3200 Message: 3202

Dear ACOM Users:

I am trying to use Acom tools for remote control but I have a problem with it. (I know I am not the only one).

It works reading the data coming from Amplifier as Forward Power, Reflected Power, etc. correctly. but it does not send any command to the amplifier or the amplifier does not receive the data.

1) If I use Acom tools to switch ON and OFF the amply it does not work (this operation is possible only via RCU).

2) If I use Acom tools to switch from standby to operate it does not switches (this operation is possible only via RCU).

Anyway if I use RCU to do (1-2) as above, the specific button into the ACOMTools the leds indicators (on/off and OPR, STB), goes lights correctly.

Have to say that I am Using the serial cable supplied with the RS-232 ACOM Interface wired as follow:

1 not connected

2 to $B"*(B 3

3 to $B"*(B 2

4 not connected

5 to $B"*(B 5

6 not connected

7 to $B"*(B 8

8 to $B"*(B 7

9 not connected

Just to make a test, I made another cable with the same configuration as above but with a connection wired from pin 4 to pin 6 but also, things does not changed.

I tried to made a third cable with only three wire as follow:

2 to $B"*(B 3

3 to $B"*(B 2

5 to $B"*(B 5

But also in this way ACOMTools does not change in any way, it still works in the same manner not more and nothing less.

I this point I think the problem is into the communication lines CTS and RTS.

Is there someone who can help me ????

I did not found any help from ACOM firm and I am so sad about it, but I do not give up at all.

Thank you

Hi Federico

Forget about the acom tools, they are scrap, a real shame for the manufacturer of such a good hardware... To monitor the output, temperature and operating status just place a webcam in front of the remote display, so you can see all paramaters when operating the amp. The Acom2000 does not need any switching for regular use, it's fully automatic, even the bandswitching. In order to switch the two buttons Operate/Standby and power on/off I soldered two cables parallel to the switches in the remote unit and switch them via a rs232-relay interface. I am running a 2000 this way for two years now in a public remote station and it works flawlessly.

Frederico,
I have not tried Acom tools with my 2000, but have not heard of many success stories. As an alternative there are a number of software packages that will remotely control the Acom very well. Look at TRX manager as one. FlexRadio has a utility that also works well. Best of luck.

I have used some quick set epoxy, the kind that comes in 2 tubes you mix together.
It holds very well but don't torque the screw down with all your strength.....

3207. Re: Nuts that hold top cover screws

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-07 15:36:30 UTC
From: kamarty456
Topic: 3205 Message: 3207

Hi Barry, hope all is well....

Those pain in the butt nuts are formally called "clinch nuts"

The key here..if installed correctly the self clinching nut will "resist" loosening caused by vibration or repeated motion.

Often an arbor type press is used to press fit them into the pre-drilled hole. I suspect whoever is installing these things during assembly has no clue how to set up his station to properly secure these things!

I have lost a few of the on my Acom too.

You can replace them. I ordered some from "Small Parts Inc."
www.smallparts.com search "clinching nuts [metric]"

You may try calling ACOM and ask for a few plus new screws.

Over torquing the screws when assembling the amplifier cover will more times than not cause the clinch nuts to twist and fail. using a very light touch or a clutch type screw driver set at position one or two is they way to ensure you don't damage the clinch nuts.

Keep in mind the Acom cover is using very soft metric 3.5mm or something like that Phillips screws. You actually need a metric sized Phillips screw driver to avoid bunging up the heads. I have used a pozidrive #1 bit and it works if careful. You may also do ok with a #2 Phillips bit but be sure it's in good shape, a worn bit will quickly destroy the screw heads.

I use a small dollop of the Quick-set type of JB Weld, applied with a toothpick. As others have commented, once replaced, the compression fit nuts/screws are more cosmteic than anything...if you tighten down on the cover screws too much, you will break the glue bead and have to start over. Fortunately, Acom uses so many screws, you can afford to have a couple broken "cosmetic-only" ones, and retain the cover with the majority of properly-anchored nuts.

barry, they are called pems. their purpose is to fall into your rig and cause it to explode when it shorts the high voltage supply. i dont why any manufacturer would use them on high voltage quipment. throw it away. dont try to reattach it.   paul w8jn

Barry,

I have had one or two come loose in past
and the epoxy or JB Weld is best way to go as I had tried installing new
ones in the past
but the metal around the hole no longer had enough material to hold the new
ones.

If I ever go back into my ACOM I will put a bead of Epoxy or JB Weld around
every one
I can get to !

This was a nasty error by ACOM and surprised they did not supply every owner
with a warning and a repair kit

Definitely not on par with the overall great quality and performance of the
world's best amp !

There□s the complex 15 pin (or so) plug on the back of the rig that you will need to wire to a phono plug.

Also, suggest the Yahoo group for TS2000 users.

Cheers,

3216. RE: [acom-list] NOS GU74B 02-2007 available FS

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-13 18:09:12 UTC
From: Kees - pa7two
Topic: 3128 Message: 3216

Hey group,

Not so much activity lately, so I have a subject to stirrrr things up a bit :-)

Guess what I received today? GU74B tubes from 07-2007 and 11-2007 production runs. Not printed with '4cx800a' (as expected), no... with the good old 'GU74B' print in small print. Looks like the we have another proof that the Svetlana factory is still making these tubes on demand.

I took a very close look, and I recognised a few parameters from the russian experts on the tubes print that changed after year 2003. These are definitely brand new tubes. No re-print or whatever.

Anyone fancy a photo? Use my personal mail my callsign at amsat DOT org.

See yah in the pile-up!

Vy 73, de Kees.

Subject: Re: [acom-list] NOS GU74B 02-2007 available FS

I fully agree to what LA8AW says here !
I got the same written response from Acom Bulgaria when I tried to order new
tubes for our clubs 2000A. In addition I tried to contact Svetlana. After some time
I got a response telling me they did not make any GU74B or 4CX800 tubes, and the
lady that contacted me did not know if such plans existed at the present time.
Acom in USA did for some reason not even answer my emails...might have been
a case of lost mails though....
Kees PA7TWO sent us some very good tubes...they match to within 2 degrees centigrade
at full power after adjusting per Acoms instructions ! And Kees never even claimed they
were matched ! :-)
The tubes have now performed excellent in many 48 hour contests. Thank you to Kees for his
excellent
service !
These tubes are not, and I repeat NOT available as a standard stock item anywhere !
Some dealers (only one that I know of....) offer them NOS and tested/matched...but it is
always a question of availability !
The are scarce,- and will be ever more so as time goes by, Keep up your service Kees !
Peter

An interesting aspect in this discussion:

Try to order a GU-74B from ACOM.

They do not sell them.....Period!

ACOM has in a mail from their Technical Dept., dated May 5th 2008 (1 year ago today!) - listed 7-8 places to get hold of replacement tubes,
and also mention Kees PA7TWO sells good tubes.

The mail is signed by Stan LZ1IU.

When checking out the suppliers on the list - Kees was 1 of 2 who answered on an email request.

ACOM users shoud be very happy that they have people like Kees - who probably spend quite a lot of time and effort to find sources for this kind of tubes.

And a mail now and then - on this list to tell that tubes is available - for me that is not a problem at all - that is just valuable informations for
owners of ACOM PA's,

No problem Pete.

But this was not the main reason of Kees' message. Kees sells those 2007
GU74b tubes for 235 euro a piece excl. shipping.

In Friedrichshafen I spoke with several Russian and East European guys
and one of them sold the 2007 Svetlana GU74b tubes for 125 euro a pair!!

So be my guest...

I really dont understand the cause of all this fuss.
The tubes are an essential part for the amplifier and all product specific yahoo groups allow "for sale" ads when they are topic related.
Every once in awhile somebody will be in the need to replace the tubes and you cant just buy them at your local hardware store.
ACOM asks much more for a tube than Kees - last time I checked was well over 300 euros (and they might have similar source as the one you are describing).
Of course Kees is not going to handle the logistics with shipments from Russia and maintain contacts there if he is going to profit only 5 euros per tube. Everything has a price.
And let me tell you about buying tubes from eBay - last time I bought a GU74b from eBay, i waited a few months before I had the tube in my hands.
I dont mind seeing that I have one more option to buy tubes and as long as Kees is not posting once a week (which he doesnt do anyway) I am OK with seeing his ads or any comercial ad concerning the ACOM products.
btw. I have no interest in his sales or any connection with him
Just my 2 cents.

Thanks Callum.

My objection is that we daily get more then enough all kinds of offers, called SPAM. I had hoped that this Yahoo group would have been free of this. If I decide to buy 'whatever' I look at eBay or I search on Google.

Ok, let's move on to more interesting subjects...

On short notice I want to write an IMHO important modification for the Acom 2000A, but probable also important for the Acom 1000. I have noticed that the two SO-239 connectors are not of very good quality. This may cause a strange effect (noise) after releasing the PTT.

Thanks to Clemens DL4RAJ I have been attended on this modification. As soon as I can find the time I will write a modification on my internetsite, together with a few photos how to replace the two SO-239 connectors. I will replace them with N-connectors, as they give better results; not only mechanical but also electronically (a more consisting 50 Ohm impedance).

The discussion continues....but check out this message no 2784 from August last year....
(throwing stones when sitting in a glass house....?)

Here is a copy:

From: Hans Remeeus <hans@...>
Date: Wed, Aug 20, 2008 at 08:26
Subject: [acom-list] GU74b for sale in Germany
To: acom-list@yahoogroups.com

GU74b/4CX800
Verkaufe 4CX800/GU74b. Jede Röhre wird von mir 24 Std. vorgeheizt. Für weitere Anbebote bitte auf www.dl3jj.de reinschauen! Preis: 90,- zzgl. Versand
Ralf Georgi - DL3JJ
Tel:0172/3520835
dl3jj@qro-shop.com

Quick translation:
For sale 4CX800/GU74b. Every tube has been pre-heated during 24 hours. Price 90 euro excluding shipping. For other offers please have a look at www.dl3jj.de

Bestseller ! New and pre-heated 24hrs!
GU74B, same as 4CX800 but much cheaper, is mostly-used tube in amps up to 800W.
Similar to 4CX800 but able to give some more watts output! You can find at: EMTRON DX1, or HF2500DXIII, or Ten TEC Titan III, or ACOM 1000 oder 2000.
Price: 90,- + shipping.

3227. Re: [acom-list] NOS GU74B 02-2007 available FS

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-16 07:50:38 UTC
From: Martin Andrew
Topic: 3128 Message: 3227

Already modified the input and output sockets to 'N' type PTFE. No
improvement in
power or stability on an Acom 1000, but I know they will not burn up in the
future.
Both sockets are not easy to work on but a little time and perseverance will
get the job done.
I have also done the 70MHz modification and find I can get more than enough
power
on this band, shame the amp won't get to 144MHz !!, I wait to see when (if)
ACOM produce
a 144MHz amplifier if not then it is I0JXX solid state.
Found problems with my driver (FT-847) giving ALC spikes, but now have an
interface
which delays RF by about 200mS, seems to work.

Personally I am not bothered if people want to advertise on here, there is a
magic key
on my keyboard called 'DELETE'.

Thanks,
Martin, GM6VXB, IO97aq

Reading the manual, it looks like a HV fault during the first part of powerup, possibly a sign of no HV available or too high. Fuses? Mains volts?

As stated in the manual, PN07 has to do with HV at power on. I had this error message several weeks ago after a very close in lightning strike which generated a large spike on the power line coming into the house.... I found one of the 2 (I believe they were 2 amp) fuses in the step start circuitry has opened... Replacing this fuse cured my problem. Jim K4JAF

I would disagree with this:

"They are advertisements only, not added value to this group."

They ARE added value! This group as the others is a *resource* and "information" is the focus of it! If my tube fails and I want to bring the amplifier quickly back online I will be facing several choices - between buying stuff from eBay and waiting for months to get it, calling ACOM dealer and waiting weeks for the amplifier to come back (hopefuly surviving the shipping) from a repair with a "new" (read NOS) $400+ tube or just buying a tube from somebody in the group (who is selling the tubes here for a long time) I would probably go with the later.
So I see the added value of knowing that I have a tube available an email away.

And when we are talking "SPAM" as you can see from the example with Hans - it is just a matter of perception. Furthermore, this group is not uber-active and such "spam" from Kees is not getting in the way of more interesting postings - for the whole month of July we had 3 (count: one-two-three) messages.

Anyway...lets put it to rest

Andrey,

If the advertiser posted without riddles, I might have a different idea but the way this poster does it, is clouding what is a post and what is an advertisement.

You have to remember, this guy causes a storm every time he does this. He must be doing something wrong else we□d all be happy with his style.

By the way, I love the moderator style here. Arguments are actually allowed. Amazing (and refreshing!).

This person Kees does things the same way on the FT2000 reflector. He had been asked a few times to "cool it down a little.

Best thing is that we all know he has found some GU74B tubes and he knows we all have heard him again and again. He will go away.

3239. RE: [acom-list] Re: NOS GU74B 02-2007 available FS

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-16 22:56:51 UTC
From: Kees - pa7two
Topic: 3128 Message: 3239

If you gents read back my original message, and I hereby I say it again for the persons who did not read to all to carefully. I only wanted to inform the Acom reflector about the fact that these 2007 tubes are now available by Russian sources.

So, yes sure, if one asks me to order a few, I have no problem with that. I have done this for some HAMs who were in the need for a spare tube. But again, that was not the point I tried to make.

The FT2000 reflector. There are users who think the radio is "all that" while other users know it is vise-versa. If one states that the radio is 100% OK, I cannot resist to reply to the message and tell him or her my findings. There are various users of the FT2000, and all with different opinions. The fact that I reply to those idiotic messages is not always appreciated. Ohh well, one can live with that I suppose, and if not it is their problem.

I've received various e-mail stating the opposite of Hans's replies, users on this reflector want to be informed about availability of tubes, and so when I find some new facts I post them here. Like I did from day one.

For M?MCX, tell me what you would like to know about my 'business', and I am most willing to tell you what you want to know. I think you will be surprised about my answers.

So, to conclude, I leave the reflector? Noway, I do not see any reason for that. If you do not like my messages, delete them. It IS that simple.

3240. re[2]: [acom-list] Re: NOS GU74B 02-2007 available FS

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-16 23:22:00 UTC
From: Jim Idelson
Topic: 3128 Message: 3240

I have no problem with Kees' information and his offer on the reflector. I appreciate hearing lots of related information and welcome a diverse range of opinions and comments - even if I don't agree. As long as they are related to the primary topic and do not include insults, please keep them coming.

Jim K1IR

>

If you gents read back my original message, and I hereby I say it again for the persons who did not read to all to carefully. I only wanted to inform the Acom reflector about the fact that these 2007 tubes are now available by Russian sources.

So, yes sure, if one asks me to order a few, I have no problem with that. I have done this for some HAMs who were in the need for a spare tube. But again, that was not the point I tried to make.

The FT2000 reflector. There are users who think the radio is "all that" while other users know it is vise-versa. If one states that the radio is 100% OK, I cannot resist to reply to the message and tell him or her my findings. There are various users of the FT2000, and all with different opinions. The fact that I reply to those idiotic messages is not always appreciated. Ohh well, one can live with that I suppose, and if not it is their problem.

I've received various e-mail stating the opposite of Hans's replies, users on this reflector want to be informed about availability of tubes, and so when I find some new facts I post them here. Like I did from day one.

For M?MCX, tell me what you would like to know about my 'business', and I am most willing to tell you what you want to know. I think you will be surprised about my answers.

So, to conclude, I leave the reflector? Noway, I do not see any reason for that. If you do not like my messages, delete them. It IS that simple.

3242. Re: [acom-list] Re: NOS GU74B 02-2007 available FS

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-17 06:14:02 UTC
From: Hans Remeeus
Topic: 3128 Message: 3242

Kees,

I too received mails from several persons who fully agree with me. They get tired of your messages trying to sell us your tubes.

Being persisting sometimes may be okay, but intrusive is not!

If you want to join a photo from the 2007 GU74b you can *upload* this photo in the Yahoo-group. There is no need to send you a message and let you know our e-mail adresses. SPAMmers are always trying to get our e-mail address, to inform us about availability...

IMHO you are asking a hughe amount of money for a 2007 GU74b. I see on the internet that you suddenly have lowered your price from 235 to 175 euro. What a coincidence, Kees!

As I already told the group: in Friedrichshafen I spoke with several persons who are willing to sell GU74b for half the price you are asking. You can negociate with every person who is doing business.

BTW; is a GU74b from 2007 better then tubes from 1989, 1993, or whatever year of production? It is not! I use my Acom 2000A for about seven years now. Almost daily, sometimes 24 hours during contests or special events. My tubes still have a gain of more then 15 dB! They probably hold for many many years. 2007 tubes do not give more gain, they do not hold longer en they don't have to be more expensive then older tubes.

I paid 90 euro for an unmatched pair GU74b (new in the unopened and original box, not a plastic bag), 120 euro for a formattted and matched pair GU74b. And 110 euro for a matched pair original shining new Svetlana 4CX800A tubes.

I doubt very much your honesty, Kees.

73,
Hans Remeeus (PA1HR)

3243. RE: [acom-list] Re: NOS GU74B 02-2007 available FS

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-17 07:34:20 UTC
From: Kees - pa7two
Topic: 3128 Message: 3243

Dear OM Hans,

Most of the Acom amps I've seen for repairs, have year 1986 - 2001 GU74B tubes fitted.

With regards your statements: you have the right to think whatever you want related to the pricing. Absolutely no problems with that. But to write that I should be expelled from the reflector is absurd.

Now that you are hinting on me asking sky high prices, some hard facts:

On very recent request of some of the Acom reflectors users I have ordered a very small batch of the 2007 year GU74B tubes. The selling price is indeed 175 Euro a tube for a 2007 year production, ex shipping & handling. When I search for a production 2007 year tube on eBay, I think the price is very competitive.

Production year 2000-2003 GU74B tubes go for as low as 80-110 Euro these days, ex shipping & handling. See my eBay auction for the proof of this. See: eBay auction# 320413034639. Also here, I am again the (or one of the) cheapest with GU74B on eBay. Take also a look at my eBay sales history and the related pricing OM Hans before making these judgments again.

One note to add here: There is no difference between a boxed or sealed GU74B. A sealed GU74B comes initially from a carton box. If one wants a 'boxed' GU74B, also no problem for me. I normally remove these carton packaging because I use a special type shipping boxes with special foam inlays to protect the tubes during shipments. 'Box in Box' so to say.

Hans, if you do not like my (or any of the) messages, just delete them. Or read only the messages you want to read on the reflector itself. If I am sending a message to the reflector, it is up to you if you want to receive these or not! It IS that simple.

Vy 73, de Kees.

Subject: Re: [acom-list] Re: NOS GU74B 02-2007 available FS

Kees,

I too received mails from several persons who fully agree with me. They
get tired of your messages trying to sell us your tubes.

Being persisting sometimes may be okay, but intrusive is not!

If you want to join a photo from the 2007 GU74b you can *upload* this
photo in the Yahoo-group. There is no need to send you a message and let
you know our e-mail adresses. SPAMmers are always trying to get our
e-mail address, to inform us about availability...

IMHO you are asking a hughe amount of money for a 2007 GU74b. I see on the internet that you suddenly have lowered your price from 235 to 175 euro. What a coincidence, Kees!

As I already told the group: in Friedrichshafen I spoke with several persons who are willing to sell GU74b for half the price you are asking. You can negociate with every person who is doing business.

BTW; is a GU74b from 2007 better then tubes from 1989, 1993, or whatever year of production? It is not! I use my Acom 2000A for about seven years now. Almost daily, sometimes 24 hours during contests or special events. My tubes still have a gain of more then 15 dB! They probably hold for many many years. 2007 tubes do not give more gain, they do not hold longer en they don't have to be more expensive then older tubes.

I paid 90 euro for an unmatched pair GU74b (new in the unopened and original box, not a plastic bag), 120 euro for a formattted and matched pair GU74b. And 110 euro for a matched pair original shining new Svetlana 4CX800A tubes.

I doubt very much your honesty, Kees.

>
> So, yes sure, if one asks me to order a few, I have no problem with that. I have done this for some HAMs who were in the need for a spare tube. But again, that was not the point I tried to make.
>
> The FT2000 reflector. There are users who think the radio is "all that" while other users know it is vise-versa. If one states that the radio is 100% OK, I cannot resist to reply to the message and tell him or her my findings. There are various users of the FT2000, and all with different opinions. The fact that I reply to those idiotic messages is not always appreciated. Ohh well, one can live with that I suppose, and if not it is their problem.
>
> I've received various e-mail stating the opposite of Hans's replies, users on this reflector want to be informed about availability of tubes, and so when I find some new facts I post them here. Like I did from day one.

Kees,

Thanks for the information, but it does not convince me about your honesty.

I did not write that *you* should be expelled from the reflector. I just don't like the way you are trying to sell your tubes. I find it intrusive, like all the other SPAM message I daily get. This is my opinion and we are living in a free country where we are able to give our opinion, without need in getting insulting.

Again; it is better to use eBay or all the other internet selling sites for your *commercial activities*. Not here, not in any Yahoo group.

Dear OM Hans,

Fortunately for me the feedback on the various selling sites and this reflector do speak a totally different 'tone', even Acom did (un-asked). One can make a judgment for its own on this specific topic I suppose. On all sites a 100% positive feedback says more than enough about my 'honesty'. (BTW -> talking about insulting...)

Reading your reply where you again did not came up with any facts :I still think you still do not get the picture. Again I have to repeat: I was informing the reflector about the fact that year 2007 GU74B tubes are made available by various Russian tube sources. Nothing more, nothing less. Many found the information I provided useful, period. And yes indeed, 'reading is an art' so we say in Holland.

My suggestion for all who do not want to read certain type of messages in general, if you un-subscribe from the daily reflector e-mail service and you read only the messages you want to read on the web page, the 'problem' is resolved. Yes, it IS that simple.

Now back to the DX I suppose!

Kees,

Feedbacks on different sites have almost no meaning. When the buyer gives a negative feedback, the seller does the same, so the buyer does not give a negative feedback. When the buyer does not give a feedback, the seller does not too. Etcetera.

BTW; is your company notified at the Chamber of Commerce (KvK) with VAT (BTW) number?

Dear OM Hans,

So, even when Acom says so it has no meaning? Come on... You made a huge mistake in a judgment which you've ventilated here , so it will be of good practice if you rectified that here on the reflector.

With regards your question: I' have stated many times before that I help out others with finding a spare tube for their amps. Non commercial and private only. But of course you knew this fact already, just like your own private sales on the various sites and homepage.

As stated in the manual, PN07 has to do with HV at power on. I had this error message several weeks ago after a very close in lightning strike which generated a large spike on the power line coming into the house.... I found one of the 2 (I believe they were 2 amp) fuses in the step start circuitry has opened... Replacing this fuse cured my problem. Jim K4JAF

It would be nice to get ACOMs advice on what is actually being tested. Assuming it is the plate voltage, it might be an idea to change the tap on the HV transformer. Maybe the unloaded plate voltage comes out too high or too low due to a change in your mains voltage.

I do not think this is likely to solve the problem, but worth a try....

Hi Trevor,

I guess these is an obvious question, but is this consistent (throughout the day and from day to day?) The reason I ask is if it is just now and then it might suggest fluctuations in the mains. I've never seen this error, but having an ACOM 1000, I would be interested in the solution when you find it. It's something we all might encounter down the road.

Good luck resolving this and please share the results of your debugging with the group.

Hi I contacted Ron in Vine antennas and i have traced the fault to a blown HV Cap on the Crowbar.

Reason for no answer from Acom is the Take month of Augest as holidays.

so hopefully i will replace cap and my acom will be alive again.

I have to be honest I was very nervous to open amp as 3000v is not my cup of tea.

I will update the group when i get the cap.

Thanks
Trevor

I am ready to sell my ACOM 2000A with extra sets of tubes...
Would anyone care to enlighten me on a fair used market price for this package?

Acom 2000A in spectacular condition/ Full output + and
(3) sets of NOS MATCHED SET Pairs of 4CX800a7's.

Thank you kindly....

You'd probably be better off setting a price for the amp and a price
for each set of extra tubes - a lot of potential 2000A buyers aren't
necessarily going to want 3 extra sets of finals.

What is a new 2000A going for these days?

Thanks for your reply Barry...
I believe that the new retail price is $6900 shipped to you door.
I would like to at least offer the tubes with the amplifier first, then if no sale, split them up after the amplifier sold.

*If you want to find the MARKET value of just about anything, just list it on EBAY...

Unfortunately with all the new rules and Nigerian type scammers out there, selling anything expensive on EBAY has become a real PIA.

And on EBAY..if you get 2 LUNATICS bidding against each other (and it happens a lot lot) - Gear can bring even more money than ACTUAL used equipment Value.....(Call it MACHO BIdding or SHARK FRENZY !)

I have bought several used ACOM 2000 and 1000 units over the past 8 years

When the ACOM 2000 sold for $5500 new, one could buy them used but still under warranty for $4000 to $4500 depending on hours on tubes age/condx and physical condition/age of amp and whether the 2000 had QUIET QSK or not. (Oh and if still under warranty)

The early (first couple of years the 2000 were made) the unit make a LOT of noise when keying in QSL mode, very important feature to many CW Ops. Of NO importance to guys that don't work CW or never use CW QSK mode. I would say that feature alone is worth $500 (ACOM silence the relay around Year 2002 I think, but someone correct me if I am wrong)

Since the NEW Price went to almost $7000, the $4000 to $4500 asking prices seemed to have moved up to $5000 to $5500. Well, first question I ask a seller, is which was the NEW price of his unit if I am going to make an offer...some people have lots of $$$ and don't care or don't do their homework Good to find those guys when you are selling a ACOM 2000

My suggestion since the economy of just about everywhere on the planet is in the tank is to list your unit on the reflector and asked for sealed bids by a certain date.

That way, everyone who wants to buy a 2000, and there are fair amount of hams whose 401K plan was decimated into a 101K plan and and still, for the moment, have a job...get a crack at it and you get the maximum amount that it will bear at that moment.....the buyer and seller leave the arena happy.... and you don't have to screw with EBAY

...or get a Seasoned Ham EBAY seller to put it on EBAY for you....

So there are some choices that can bring you maximum amount for your unit.

..and yes, good to give buyer first dibs on tubes...and I am sure you can take sealed bids
on those too if buyer doesn't want them all.

73, Dennis N6KI
San Diego*

P.S. - How much do you want for the amp ..... ;-)

Len, it looks like you already listed this on qth.com for $6200. I
don't know how much you factored in the 3 extra sets of finals, but
$6200 is going to be a big pill for someone looking for a used 2000A
to swallow. I still think you're better off setting a price without
the extra finals and giving the amp purchaser the option to also buy
as many of the 3 sets as they want. After you sell the amp, the tubes
will be easy to sell since there's a high demand for them.

I agree with N6KI about the approx going price for the 2000A, but I
believe the QSK noise issue was fixed earlier on, perhaps toward the
end of the first year of production (2000?), by acoustically isolating
the vaccuum relay.

I bought mine 8 months ago for $ 5000.00 and it was in excellent condition, (I drove from southern New Jersey to Ohio to pick it up) but the tubes were a little weak and the amp had 6,000 hours on it. I took it to The Dayton Ham fest this year and gave it to Willem and he checked it out, realigned it and put 2 new tubes in it. The total bill with shipping came to

$ 557.00..... So take it from there.. The money part never came into my mind. I wanted one and I got one!!! Take in the fact that there are a lot of people out there who would love to own one and if someone wants it badly enough they will pay what you are asking. As my real estate instructor told me a long time ago "THERE IS A SEAT FOR EVERY ASS" Don't give it away !!!!

If I were you I would sell the tubes separately. Let me know how much you are willing to sell a set of the tubes for, as I know 3 other guys right here in my county that own one. good Luck!

Best regards

Ray W2RM

3268. Pelicase

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-21 15:13:03 UTC
From: mw0jze
Topic: 3268 Message: 3268

Hi all,

Have any of you 1000 owners ever gone /p with your amp??

I recently did an IOTA MW9W and took the 1000 with me. It was well packed in the original box and well water proofed as it was a boat crossing. After the event I thought it would be worth my peace of mind and the safety of my amp if I invested in a Pelicase (water and bomb proof) Question is this, what's the best size? Have any of you bought one? If so any advice would be welcome, cheers.

Anthony MW0JZE

Doesn't shipping the ACOM 2000 with the transformer installed increase the risk of destroying the components inside. The transformer mount is not designed to withstand shock and movement. That is why the ACOM 2000 and transformer come in separate boxes.

This is a very correct and wise conclusion.

Unfortunately there are many examples of shipping linear amplifiers with heavy transformer, who were severely damaged because the transformer was not removed and shipped seperately.

Always remove the heavy transformer before the linear amplifier is shipped. This costs about 5 to 10 minutes time and will prevent a lot of sorrow.

Acom has understood this very good; their packages (as well as their linears) are excellent!

The other error he makes is thinking that the remote control head is using RS232. It is not. It merely utilizes a DB9 connector but that is as close as it gets to RS232.

Joel,

Well, it appears that RSGB does not publish "Features" articles on the net which is where the ACOM article resides. :-(

Hi Joel,

I found the article online. You can download it from here -
http://depositfiles.com/en/files/q0whrcqkb

it is in DJVU format so you'll need a djvu browser - there are plenty of free djvu standalone browsers and IE plugins on internet - just do a google search.
Honestly, I didnt find the article very interesting - it is more of a travel diary IMHO. It lacks details about the amplifier manufacturing facility but speaks of ACOM's sound dampening wall at the local airport (huh?). This article is just a waste of space on the pages of RadCom. The picturs are not that great either. I dont thik you are missing much!

It lacks details about the amplifier manufacturing facility but speaks of ACOM's sound
dampening wall at the local airport (huh?). This article is just a waste of space on the
pages of RadCom. The picturs are not that great either. I dont thik you are missing much!

3282. line voltage display/monitor adjustment

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-26 01:19:07 UTC
From: kamarty456
Topic: 3282 Message: 3282

I have decided the Acom 2000A line voltage measurement is way off ....

Using a digital voltmeter I measure my 240VAC line at the outlet and get 245VAC.

The Acom 2000A RCU display shows 252VAC and as the line varies so does the Acom, but there is usually about a 7VAC difference.

Looking at the schematics...interface circuit board sheet 7 of 8
I have located RP13 a 50k-ohm pot JP7:22 so that should be the calibration potentiometer.

Now if memory is correct, the interface board is the board behind the front cover? I will need to remove the entire top cover to access the screws to remove the front cover..right?

Now one more set of questions..I notice my heater voltage is around
13.2V other than diving past a powered transformer and high voltage, is there an easy test point to use to verify the actual heater voltage as it may also be off. The adjustment for heater voltage is on page 6 of 8 on the interface board and is RP12.

Thanks

Martin KA7GKN

Hi Marty,

I believe you are correct about the Mains adj. However, look on page 15 of 43 sheet 1 of 1 and you will find JP1:2 hvmi. That suggest that that RP12 may be the high voltage measurement. Heater voltage may more likely be RP16 on pate 25 of 43 sheet 7 of 8. See JP2:4 on page 42 of 43 sheet 1 of 1.

Notice also the RP2 1k main adjustment on page 7 of 43 or sheet 2 of 6 that will affect all analog readings. You will see that this is fed by the multiplexer chips on page 10 of 43 or sheet 5 of 6 that take in all the analog readings. In my case several analog readings are suspect. Specifically: Fwd-P, Mains, Fil-V, IF-Front and Rear. However Drive checks slightly low. It seems that some of the amps were not carefully calibrated before they left the factory.

I wish you all the best. Let me know how it goes.

73,

Hal - K4HW

3284. Transporting the ACOM 1000

Yahoo group: acom-list (1999 — 2009)
Date: 2009-08-29 18:24:09 UTC
From: n7avk
Topic: 3284 Message: 3284

Hi Folks,
Sorry I'm late on this. I've taken my ACOM 1000 around the world, getting to FT5XO and back and then again from the West Coast USA to ZL8R and back. I've used the Pelican 1650 with the "pluckable foam". Total weight is 70#. The amp has travelled just fine with no problems and that is with the power supply left in the amp. I mean what are you going to do...take the power supply out and carry it along in your purse or a second container?..which gets spendy. I had to pay excess weight to the airline pirates, but you do what you have to do to get where you want to be.
I use it at home as the amp for my second radio in a SO2R setup. Used it on all bands for the DXpeditions including 6M EME, although it has its best value for us on the low bands where the QSB and noise and all is worse than on 10-40M.
73 and I remain,

Lew,

The 1000 is perfect for what you describe and the transformer does not need to be removed for shipping/transportation.

With the 2000A, the transformer is just too heavy to leave it in the chassis. While it may survive shipping with the transformer installed, it's probably not worth the risk.

Agreed.

Although I have a professional flight-case and I leave my transformer in all the time, I only transport it in the back of my car - anything else and the transformer would have to come out.

From: Hans Remeeus
Topic: 3288 Message: 3289

Hello Marty,

Quote

The modification is made on the INTERFACE PCB and it requires to remove
the front panel. You should first disconnect all cables from amplifier,
especially the mains cord! Then remove the top cover using a Philips-2
screwdriver. Do not press the screws excessively in order not to push
any captive nut out of the chassis.

Four M3x3 screws on bottom-front and two more on top hold the front
panel. The bottom four screws are with cross-recessed Philips-1 heads
while the two on top can be with a straight slit (flat screwdriver).
Unscrew four bottom screws the first and only after that - the two on top.

After removing the front panel, you may place it near the amplifier
without disconnecting the power switch. Be very careful not to mixup
wires if you would prefer to disconnect it - the wires are labelled
according to the numbers printed on the switch.

Please find the INTERFACE PCB in the right of the chassis - see the
attached picture Front_View.jpg. The left-bottom corner is shown in
details in the picture Ints_smd_EBS1.jpg. Add a 100-220nF 50V capacitor
to the via holes pointed with yellow arrows. The additional capacitor
will connect in parallel to the original 100nF in order to double to
tripple the time constant of the EBS delay.

Now look at the picture Ints_smd_EBS.jpg. Add a wire jumper between the
via holes pointed by two yellow arrows as shown with a blue line in the
picture. This will connect the emitter of the transistor Q4 in order to
fully block the EBS operation i.e. the tubes will be operated with the
high-level idling current always when the PTT is pressed, whether the RF
drive is present or not. No additional capacitor would be needed in this
case.

Hello George,

This mod is for our HiFi operators.

Please read what Stan LZ1UI wrote about this mod:

Quote

ACOM does not recommend introducing this modification unless you have
EXTREMELY high sound-quality requirements. The difference can be
detected only at very small distances, under 1-2km. Normally you do not
need it and all ACOM2000A, ACOM1000 and ACOM1010 units up to date have
been produced without such a modification.

You should know that although possible, this modification sets a
compromise between the temperature regime and the signal quality. The
minimum capacitance which satisfies your quality requirements is
recommended. Full EBS elimination should be avoided unless you have the
additional external fan installed.

Unquote

I will not implement this mod, for the mean reason that I always get
excellent audio reports. Nothing to complain.

But sometimes even 'excellect' is not good enough ;-)

For this reason some operators choose a linear amplifier with 3CX800
triode instead of pentode or tetrode tubes. For the audio freaks the
triode gives a bit better audio. Same as the difference between Class A
and Class AB amplifiers. I must admit that I never heard the difference...

IMHO it's all in the margin, but could be a very interesting and well
respected part of our hobby.

3293. ACOM-1000 new trick

Yahoo group: acom-list (1999 — 2009)
Date: 2009-09-05 23:01:16 UTC
From: n7avk
Topic: 3293 Message: 3293

I order a new ACOM 2000A, put down the phone and fire up my 5 year old ACOM 1000. It warms up OK but now has 0-10 watts showing out on the forward power and power out checks. I disconnect the coax from the radio. Same readings. If I try to put the amp into transmit mode it shuts down with admonition of "hot switching". If I can get it into transmit mode when the forward power reads 0, it then seems to function just fine except for showing small amounts of power out-(1-10W usually) when I'm on receive.
Seems like a component goof to me..but has anybody had a similiar thing happen to their 1000? Any ideas before I send it off to the ACOM hospital?
Thanks.. 73 and I remain,
Lew W7EW/W7AT

Thank you Hans for your reply.
I do have the external cooling fan and have never experienced
cooling challenges.

I keep vacillating between leaving the 2000A alone and modifying
the electronic bias.

As of right now I'm leaning more to "leave the 2000A alone"

I decided to replace my Sony mini-disc recorder with a Marantz PMD661
digital recorder. This unit although expensive has much better and newer technology
compared to the Sony ATRAC-3 compression.

Since my "live audio" routed through processing etc. does not exhibit and electronic bias
crunches, I am more suspect of my mini-disc as it plays through the same route.

I'll keep you informed to my progress

Hello Marty,

I would leave the 2000A as it is. Mine is about six years old, almost daily usage, and still like it very much without any problem. Same tubes as six years ago and still 15 dB gain left from the 15,5 dB. The only cons I have are the two SO239 connectors; I will replace them for N-types.

Congratulations with your PMD661! We still use enjoyable Marantz HiFi equipment from the 90's; solid, heavy and excellent audio quality.

Hello Ted,

The SO239 connectors I have in my 2000A are of bad quality. The hole is too wide for the pin of the PL259 connector. This sometimes causes an arcing failure, while switching from receive to transmit and the other way.

N-connectors are better from different points of view. They fit and close better. You have less change for dirt or dust in the hole. Their isolation is better. They have a better and steady 50 Ohm impedance.

Nowadays the N-type connectors are not much more expensive then the SO239 connectors. For brand new Rosenberger or Suhner N chassis connectors we pay 2 euro. The N-type cable connectors perhaps are 2 or 3 euro more expensive then the PL259.

When you find it difficult to replace the SO239 by N-types, then use good PL259 (e.g. from Amphenol) connectors who have a bit bigger pin (larger in diameter). I only use this type connector (PL-7 Clamp), which is of excellent quality:
http://www.kabel-kusch.de/UHF-Stecker/pl-7-cl.htm
http://www.kabel-kusch.de/Montagen/PL-7-Clamp/montage_pl_7.htm

I advice other users to check their connectors. They are very important parts of the transmitting circuit! The chain is as strong as its weakest part...

Hi Callum
I asked this question to Stanimir in Acom-Bulgaria few years ago and his reply was that it should be fine up to 20m, they successfuly tested it. He as well recommended to put ferrits on the cable for possible interference. I myself are using 7m length cable and never had any problems.

I was talking with Jay Terleski from Array Solutions today. They're in the process of becoming a distributor for Acom (it's not yet clear whether Krassy's company will continue to sell and support the amp in addition to Array Solutions -- stay tuned.)

Jay said they have matched, tested NOS 4CX800s in stock for $550 per pair (I bought a pair on the spot.) He said they will be getting brand-new 4CX800s from Acom (not the military version, but brand new Svetlana 4CX800s) and they will sell for $500 per tube.

If you need a pair of tubes for your 2000A, the NOS tubes are a heck of a deal.

Dick,

Just to clarify, we ARE an Acom distributor and Factory Authorized Warranty Repair center for Acom amplifiers as of Dayton 2009.

The question is whether Krassy is continuing, and in what capacity. Krassy's status is the only unknown - not Array Solutions.

The NOS tubes are in very limited quantity and once they are gone, they are gone. Please keep in mind that these tubes do not fail routinely. They are very rugged and failures are very rare. Svetlana *is* making new tubes, and Acom provides Svetlana with components that are used in their production facility for the tubes. The old GU74B tubes - the military ones that were dull and grey in appearance - and cheap - are no longer being made. Svetlana now only makes the 4CX800 and it looks more like an Eimac tube, being polished and shiny - and with the appropriately Eimac-like high price of about $500 each.

Just an example, I am still using my original tubes in my Acom 2000A that I have been using for about 12 or 13 years, including dragging it back and forth to & from Antigua several times as airline baggage, in multi-ops being abused for years here in Texas, and in virtually every contest over the last 12/13 years - SSB, CW and RTTY.

So, despite the tube panic expressed here over the last year or two, there is no reason to rush out and waste your money buying tubes you may likely never need. Save your money for other things.

73,

Bob Naumann W5OV
Array Solutions

Hello Bob,

This IMHO is an excellent and very wise advice of you!

The GU74b is made for such kind of "abusing" operations you have
mentioned to us. It is the so-called 'military version' of the bright
shining and very expensive 4CX800A.

It is much better to spend some extra money e.g. on a very good antenna
analyser, in order to know what the antenna is doing in combination with
an Acom linear...

I find the rush to purchase GU74B tubes very interesting for Acom owners. I think a lot of us including myself would like to ask this Acom owners list a very simple question that will clear up any real rush to obtain any placements.

HOW LONG BE IT HOURS OR YEARS THAT YOUR GU74B TUBES HAD TO BE REPLACED?

Take into consideration if you pushed the tube(s) past the spec that the tube was intended for. Your comments would be interesting to view on the reflector.

Are you really going to spend another $1,000. for what possibly may be needed if ever?

Hello Joel,

With all the safety features the Acom linears have, the tube(s) will
last for decades! Perhaps 10,000 hours of operations, or even more.
Depending of course on the way of operating your rigs and amplifier and
how you treat them. One cup of coffee could be the end...

Please don't worry about your tubes:

With indirectly-heated tubes, I am more concerned about regulating filament voltage to the manufacturer specs than anything, including grid dissipation.

My line voltage here runs 252 VAC and varies little. The 2000A does have an excellent tapping system through the power supply compartment as well as being able to match the line voltage through the RCU menu.

I sold my 2000A back in 1999 (the first unit shipped to the U.S.). I continued to use an Alpha 77Dx with a single 8877. Since that time, I've gone though three tubes, all with filament problems, owing to the high line voltage here. To finally deal with the problem, I killed two birds: I always hated the fact that the filament return is on chassis ground and I was always concerned that the Filament V was outside Eimac's specification with my high line voltage. I decided to add a balanced filament choke which raised the filament return above chassis ground. Just enough IR loss through the choke brought the filament V down to the target value of just barely under 5.0 volts. So far so good.

With the above said, the GU74Bs in the 2000A should run nearly forever if the amp continuously monitors filament voltage and grid current to ensure that it's operating within the tube's specified ratings.

Hi all,

Few reasons for worn out GU74B tubes are:

1 - The most worn-out tubes I've seen were caused by usage with way too high temperatures. The air-filter was fully blocked by dust in all these cases. I've repaired a couple of Acom-1000 units with this phenomenon.

2 - Other causes could be "I tune the amp just once in the middle of the band and that is it". Meaning no re-tuning takes place when the frequency has been changed in the same band.

3 - Tube has been designed for approx. 800 watts. So, if you drive a tube over the specs, do not expect a long lifetime?

4 - Filament & HV voltage set to high. Seen a few times with Acom 1000 amps. For tube life it is better to have the filament slightly below the 'normal' working voltage. The Acom amps allow the end-user to re-set the taps on the transformer to a lower voltage than the actual mains voltage. These transformer tap setting raises the high and filament voltages substancially, and thus amp produces more output power. Well that is, for a shorter period of tube life time of course!

5 - Just a bad tube from day one. Tube dies slowly during usage and within a few years it needs to be replaced. No special signs whatsoever. Bad luck. The amps have a very good protecting mechanism anyway.

6 - Any other missing reason...

Just my two cents on the topic. (I can see the 'flames' already hitting my inbox again...).

Subject: Re: [acom-list] RE: Do you really need replacement GU74B tubes

Hello Joel,

With all the safety features the Acom linears have, the tube(s) will

last for decades! Perhaps 10,000 hours of operations, or even more.

Depending of course on the way of operating your rigs and amplifier and

how you treat them. One cup of coffee could be the end...

Please don't worry about your tubes:

Yes, you need replacement tubes !
Had an Acom 2000A on my desk for repair, 2 years old, barely used - only 35 hrs on the clock. 1 tube defect......
Better safe than sorry....

I had a Dentron MLA2500 back in mid 80' - the one with the 8875's. Price at that time was $500,- for a matched pair from a well know US resource.....didn't buy a spare set, as it was too expensive. Tubes said good bye, didn't manage to get hold of new/old ones.......(this was years before Internet and eBay.....) Guess who did regret that I didn't buy the spare set.......

Tubes DO fail occasionally - I had one final fail in my 2000A a week
before CQWW. I guess it's a matter of choice and beliefs, but I got a
bunch of spare finals myself.

Future price of $500 per tube is just plain ridiculous.

Why is it so desirable to have a "matched pair" of 4CX800 tubes in an Acom 2000A?

I agree with Barry. As a serious contester, I've built a fair amount of redundancy into my station. After all, CQWW CW comes around only once a year. Losing one of my amps just before or during that contest could significantly impair my performance, possibly ruining a lot of time and/or money spent getting ready. Having a spare set of tubes makes a lot of sense.

That said, I've been running my 2000A on the original set of tubes since about 2001. I've also been running an 87A, which gets far more use in contests than the 2000A, on the original set of 3CX800s since 1995.

About 10 years ago, I had some problems with one of the tubes in my 87A and bought a spare 3CX800. It turned out to be an improperly seated tube, not a bad tube, but it's been nice to have that spare on the shelf. I sure wish I'd laid in a set of 4XC800s when they were $200-$250 for a pair! There's no way I would buy a pair at $1,000, but felt that at $550 it was an OK investment. I'm sure they'll hold their value.

As with most amplifiers with multiple tubes, the tubes are working in parallel pulling their load together. If you have a pair where one of the tubes has a slightly different gain (lets say it is higher), this tube will be loaded more than the other and it is going to work harder. Btw. this is how you can detect lack of "matching" - by monitoring their individual temperature under load.
So when you have a matched pair, both tubes have the same working point and will wear out evenly.
A "matched pair" is desirable in any amplifier with multiple parallel tubes. On the other hand, it depends on the tolerance of the parametters during manufacturing - if the tubes are generally made with strict tolerance their parametters will not vary much from tube to tube and the "matching" might not be a thing for concern.
That's why is a very bad idea to have tubes made by different factories in the same amp - for instance in a 572B amp like SB-200 to have one tube made in China and the other made by Svetlana (Svetlana's 572B are with much higher gain)

Ill play devil's advocate - all in good spirit and as a learning opportunity for all of us - me included...

First - one tube works harder than the other. True enough, but so what, as long as they are both operating within their specs?

Second - In a grid driven amp with lot's of negative feedback like a 2000A, the mismatch that appears as difference in temperature is not due to gain differences in the tubes - this get swamped out. The difference is due to a difference in cut on/off voltage. One tube is biased further into conductance, further up the load line if you prefer, but this doesn't matter either as long as neither tube is driven substantially further off during the bottom of each cycle (this is a call AB1 amp, with medium Q tank) than the other. The worse result will be some increase in 3rd and 5th order IMD, but it takes a very large unbalance to cause much IMD with a tank Q above 10 (like we have here).

I think of it as simplistically as two resistors in
parallel. Assume they are nominally 100 ohms, with a 10%
tolerance. If you want them to carry the same current, dig around in
the box until two measure the same resistance and use that pair. It
doesn't matter if they are both 90, both 100 or both 110. You don't
want a 90 in parallel with a 110 or the 90 ohm one will have to
dissipate 20% more heat than the 110 one. That's how I think of
matching tubes in an amp.

3317. Error Decoding and Excel sheet

Yahoo group: acom-list (1999 — 2009)
Date: 2009-09-18 21:18:11 UTC
From: jacksnelson2001
Topic: 3317 Message: 3317

Good afternoon all. I have a 2 yr old 1000. I have a small piece of plastic sheeting attached over the fan to keep dust out when the amp if off. It's taped on one side and flies open the minute the fan turns on. Yesterday, just a few seconds after turning the amp on, I noticed the sheeting was not moving.

There was some air, but very little. Then I noticed the error code 1APN25 000000 000600. From the manual, it seems this is happening in the Power-On cycle (yes) and that it has something to do with screen grid current. Am I interrepting this correctly, and what does it mean?

I see reference to an Excel sheet for decoding help, but didn't see it on the Acom site, but apparently it's been send to members of the list previously from what I read. I didn't see it posted in the Files sections. Can someone sent it to me?

Thanks for taking to time to read this.

3318. serial numbers don't match...

Yahoo group: acom-list (1999 — 2009)
Date: 2009-09-19 19:40:40 UTC
From: kamarty456
Topic: 3318 Message: 3318

I get the message"serial numbers don't match" after the initial warm up time of my 2000A. Then after displaying for a few seconds the amp finishes the warm up cycle and all is working perfectly.

I have forgotten how to eliminate the error message or what has caused it.

I did send the amp to Acom for service but included the remote control unit [RCU]

Anyway, this is merely an annoyance and I'd like to remove the message

Thanks Martin KA7GKN

3319. Acom 2000A-IP 530 mA- Should be 0

Hello !
Our Acom 2000A has a problem :
In STBY everything is OK..it wakes up as
usual. When countdown is finished it sits there
apparently OK. As soon as OPR is entered it trips
telling us IP is 530 mA-should be zero. This is without
keying/PTT and no drive.
In STBY it shows G1 is at -120V..this seems normal.
I understand it as plate voltage is applied at the end of the coundown
cycle,- this should exclude HV supply problems as it shows no problems
at this point ??
Likewise there does not appear to be any internal grid/cathode short because
the -120V keeps up nicely ?
I also thought the grid voltage stayed at blocking level until PTT was keyed ??
This should exclude problems in the opr G1 voltages ??
Is my logic wrong ??
Any ideas please ??
73 and thanks
LA7SL

I had similar symptom....
off to Wil & Krassy ....(the American distributor).

The Amp section was fine , the brainy part was sick.

it was a about seven Ics that came back in a bag with the AMP.

My recollection was that they were all from the various input lines
to the CPU sampling the various voltages.....

Since it was a No Charge repair.... I did not want to bother them
for too many details.

To simply close this discussion here is an update.

I have received the Marantz PMD661 digital recorder. I have it installed using the TOSLINK optical output of the Icom IC7700 via an
optical to digital S/PDIF adapter into the PMD661 digital S/pdif input. The output is analog line out routed through the audio rack.

If you recall, using the Sony MZR700 mini-disc recorder I experienced an anomaly with the 2000A electronic bias. It sounds like RFI or a RFI chirp. This was suspect to the ATRAC-3 compression.

The Marantz PMD661 does not seem to exhibit the above anomaly!

Therefore no challenges with the ACOM 2000A and all is well.

Hello Martin,

Very good to read your message!

Actually I received some complaints about my audio a few years ago. All heard a very little 'ripple' in my audio. I tried everything to get rid of it, but without succes. As the ripple was just very minor I thought I had to live with it. Untill we moved to another house. Nobody heard the ripple again... Probably it just was a little bit of RF feedback from the antenna or antennafeeder.

3323. Amp comparison 2000a and 9500

Yahoo group: acom-list (1999 — 2009)
Date: 2009-09-22 20:19:08 UTC
From: barbiekenw
Topic: 3323 Message: 3323

I am not tryng to be cute here, but I would like to hear from someone who has used both the Acom 2000A and the Alpha 9500.

I own an Acom 2000A for 3 years which has been very has been a pleasure to operate. I also owned an Alpha 87a for 17 years which also was super nice, repairs are expensive. I sold the 87a as it is getting a bit old. The ACOM is at another location, so I am getting a replacement for the 87a.

I intended to replace the 87a with a Alpha 9500, but I find a 6 week wait (AT LEAST you can bet), another ACOM 2000A could be shipped tomorrow. And there is a difference of $1300 -- shipping considered.

I am leaning toward another ACOM 2000A since I really do not find the differences look like $1300 to me. Perhaps the single alpha tube would be easier to replace in the future, etc. I do not need an amp that switches between 4 antennas.

If you have used/owned both please reply offline to me to discuss your evaluations.

((((there is a difference of $1300))))))

Has the Acom 2000A went up in price??

Last I remember was $6500-6800 for the Acom

And

$10150 for the Alpha 9500

That's $3350 - $3650 difference not $1300

And that almost alone would make my decision so so easy.

Subject: [acom-list] Amp comparison 2000a and 9500

I am not tryng to be cute here, but I would like to hear from someone who has used both the Acom 2000A and the Alpha 9500.

I own an Acom 2000A for 3 years which has been very has been a pleasure to operate. I also owned an Alpha 87a for 17 years which also was super nice, repairs are expensive. I sold the 87a as it is getting a bit old. The ACOM is at another location, so I am getting a replacement for the 87a.

I intended to replace the 87a with a Alpha 9500, but I find a 6 week wait (AT LEAST you can bet), another ACOM 2000A could be shipped tomorrow. And there is a difference of $1300 -- shipping considered.

I am leaning toward another ACOM 2000A since I really do not find the differences look like $1300 to me. Perhaps the single alpha tube would be easier to replace in the future, etc. I do not need an amp that switches between 4 antennas.

If you have used/owned both please reply offline to me to discuss your evaluations.

From: kamarty456
Topic: 3288 Message: 3330

I did experience a similar RFI anomaly years ago and I actually tracked it down the my Alpha Delta 4 position antenna switch.
I replaced it with an ICE 6 position switch and like magic no more anomaly.

Now not to start a product war....I had the alpha Delta switch 10+ years [purchased new]and also used it with an Ameritron AL80A without any challenges.
I also had to open it up a couple of times to adjust the contacts.

In the end The switch was the cause as since its replacement I have never had any such anomaly.

Hello Marty,

I forgot to mention that the 'ripple' was only heard during SSB transmissions with the Acom 2000A.

Switches like the Alpha Delta indeed could cause such problems like you mention. Another well known problemsource is the 90 degrees coaxial M connector; it has a small feather inside. It is to be adviced not to use those kind of connectors. Again there is a significant difference between M- and N-connectors!

FYI :

90 degree angle M connectors are available in different qualities. Pretty easy to find out which one to buy. If you move the inner pin on one side, and you do not see the inner pin moving at the other side of the connector, I bet you have a low quality one with a feather inside.

I've got brand Amphenol 90 degree M connectors, which I measured / sweeped and proofed to be very much OK up to a few 100 MHz. These are the silver type, in a clear sealed plastic bag with Black prints.

3333. Acom 2000K vs Alpha 9500

Yahoo group: acom-list (1999 — 2009)
Date: 2009-09-23 13:12:20 UTC
From: barbiekenw
Topic: 3333 Message: 3333

I received some replies to my email address.

Summation:
1. Early 9500 were an absolute disaster.
2. The current manual with the 9500 is still not good and has been being rewritten for a year. Whole appendix missing where things get explained.
3. Owners of new Alpha 9500s are as pleased as punch with the performance. Most all have owner multiple alphas.
4. Molly and crew try hard, but there is no backup and no cross training. Some things get ignored or forgotten. Who knows what happens with new ownership.
5. Right now Array Solutions is gearing up for the ACOM - no stock for 2 weeks - but they have plenty of HL-2.5KFX. It is unclear (to me) if they will service ACOMs out of warranty that they did not sell.

New price for Alpha 9500 is $7995, plus $200 shipping to me, $8200.
Acom 2000a is $6850 shipping included.

I would love a single 8877 amp as I am a bit afraid of ACOM tube replacement availability, but I doubt I will live long enough to need my tubes replaced (pund intended).

After considering Alpha 9500, HL-2.5KFX, and ACOM 2000A, I am getting the ACOM *.

I would love to have the instant-on of the HL-2.5K but I think it is not robust enough for RTTY contests. You just can't have everything you want! One woman at a time! *

*unless some late information changes my mind. HI

Ken

I too had an Alpha Delta switch some years back...it leaked RF and/or had bad isolation between the ports. Depending on freq & power level, it caused strange things to happen. I changed the coax switch to one of the older (and less pretty, and without impulse suppressors) B&W coax switches and the problems went away.

YMMV

These switches have been "improved" in the last couple years, maybe that
has helped reduce problems as described herein.

Ken,

Unless you are going to use the Acom 2000A at W1AW for broadcasting, you do not need the auxiliary fan.

I have had one on my Acom 2000A since I got my amp back in 1997 and the aux fan has only come on once in all of that time. It ran for a couple of minutes and shut off once the temp dropped inside the amp. I was surprised as I heard it, but didn't know what the noise was. It was about 100 degrees in the shack that day.

73,

Bob W5OV

Ken,
I not familiar with the broadcast applications for the 2000A but if you are into RTTY contesting you need the aux fan. I installed the ACOM optional fan. That bad boy gets real hot without it. It will get up to 8 bars = 80C or 176F without it. That would make 100 degrees in the shack feel like a cool breeze. I keep the heat and noise out of the shack with it installed down in the basement. It keeps the basement warm during winter contesting months :). The aux fan is not needed for CW, SSB or even casual RTTY.

Ralph,

What output power level are you running when you do RTTY contesting and therefore need the fan?

Hi,

I installed myself the aux fan in my Acom 2000A.
During normal use it is off, but during SSB contest it is on every a few minutes.

It is worth to install it because the fan is quite cheap (mine is roller bearings type and works at 24 VDC) and it prevents the tubes agains high temperature.

ACOM specifies that the auxilary fan must be mounted for continuous carrier mode transmissions longer than 15 minutes. RTTY contesting meets that criteria especially when you are in Run mode. The power level I use depends on the contest, band conditions and activity etc. It's always within ACOM's 1500W PEP limit and on the average much less. You have to be careful and operate within the specified limits. Continuous carrier modes deliver maximum stress and heat. My suggestion is to follow ACOM's advice and be safe.

my fan SEEMs to be on all the time ..very slow awaiting for the
DT5 to come up again.
unless the internal fan provides enough to make the blades turn with
some torque,,,,

Hard to be down there to see if it runs fast/faster when running the
2000a ...up here.

"Out of site" ... the amp is below my feet also .... so I just went
down and stopped that fan, it sure seems to be powered all the
time....24 vdc i think
Shipped from ACOM that way ...

bill

Hi,
I got the aux fan installed. It cames installed when bought the amp from VINECOM. Never heard the fan running during the year I have been using the unit. I hardly ever participate in Contest but lot of dxing with the amp on almost every minute at the radio. 95% of the time the amp is set at 1kw PEP. Never run more than 500 wts on rtty so I would say I´m very conservative. The amplifier is located in a well ventilated area (with two big blowers behind) outside the operator desk. Mine never gets more than 60º C and it ocasionally reach 70ºC during the hot summer days. In my opinion and in my particular circunstances, the aux fan is not needed. 73

Hello Fernando,

Thanks for your interesting information.

I run my Acom 2000A for a couple of years now. Mainly for normal/daily operations (I am leader of some nets), and a few times a year during a contest. I don't have the fan installed.

In the group I have read that the fan is not expensive, it is temperature regulated and makes hardly noise.

What could be a reason (or reasons) why we should *not* install the fan?

Hans,

The point is that it is not necessary in "normal" use.

If someone wants to spend the extra money, that is their decision to make of course.

I did, and as I said, I only recall one time the fan came on in 12 years of heavy usage - including RTTY contests. However - not at 1500w output RTTY - probably about 1K for RTTY is enough.

Hello,

That depends on your Voltage setting of the transformer inside the amplifier; I hope it is 240 Volt.

What type Acom linear are you using?

E.g. when the HEATER led on the remote control of the Acom 2000A is blinking very often, then you may keep an eye on the Filament Voltage reading on the display of the RCU.

Acom told me that some higher Filament Voltage (e.g. 13,1 instead of the nominal 12,6 Volt) will less harm the tubes, than when the Filament Voltage is too low (e.g. 12 instead of 12,6 Volt).

Acom writes: "If even more severe mains voltage deviation occurs, the auto protection would trip, the red "PROT" LED will flash, and an appropriate text message will be issued on the display of the RCU". This is about the 2000A protection.

3351. When it's time to replace the tube(s)?

Yahoo group: acom-list (1999 — 2009)
Date: 2009-09-25 20:36:06 UTC
From: Ger
Topic: 3351 Message: 3351

I know that this topic has been discussed several times but I have the ACOM 1000 here on the desk. It's 2 years and 4 months old now and not heavy in use. Maybe average it TX around 1000W out 15-20 minutes per week. In standby (powered on) for average 8 jours per week.
The output is the same but I have to drive it with pretty much more input compared to when it was new.
On 160 meters I need 75W drive to get 1100W out, Ia = 650mA and HV in iddle = 2736V. Gain shows 11,5dB on display.
On 40 meters I need 80W drive to get 1060W out, Ia = 680mA and HV also iddle = 2736V, Gain shows 11dB on display.
On 6 meters I need 50W drive to get 1050W out, Ia = 700mA and HV also iddle =2736V, Gain shows 13,5dB on Display.
Highest output is on 12,15,17,20 meter: 1175W but more input results in a " reduce driving" warning.
Average the gain is 1 -1,5 dB lower then before when new. Do others also see the same detoration in gain?
I have a home made PA with an Eimac 8877 for six meters and since I build that Amp in 2000, the gain and output never changed till date.
All power input and output values measured with a BIRD 43.
Is it time to exchange the GU74 or are the values I put here the same as others see?

Thanks and best 73's Ger PE1CZG

Ger

I find a loss of gain may be < 0.5dB (no more) since the amp was totally NEW. However, now gain is perfectly stable. Gain displayed by ACOM 1000 is 12dB on HF bands (40m-20m) while calculated gain with LP-100 is 11.5 dB. I consider a slight loss of gain is possible after firts hours of use ; but I am not a specialist !

Also, I consider the ACOM1000 has a maximum safety limit output of 800W (500W is the current output I use, legal limit in France). While it can support more, I think 800W preserves the tubes for a long time. Certainly 1100W is too much.

Best 73, Laurent

3353. 250 Volt supply, ACOM 2000a

Yahoo group: acom-list (1999 — 2009)

From: barbiekenw
Topic: 3353 Message: 3353

Summarizing the offline emails betweens Hans and me,

My Acom 2000A is set up for 240V, my line voltage reads 246.6 volts.
Best is to set DEF menu MAINS VOLTAGE to HIGH.

3354. Re: [acom-list] Re: When it's time to replace the tube(s)?

Hello Laurent,

800 Watt indeed is a very good and safe limit for only one 4CX800A/GU74b
in the Acom 1000.

More output, and especially above 1,000 Watt, could not only harm the
tube but also other parts of the linear amplifier, according to Acom.

Same with the Acom 2000A. Yes, it is possible to use 2,000 Watt or even
more output, but it is more safe and far more wise to stay under 1,500
Watt. If you care about your linear amplifier and the quality of your
signal...

Some people I know use the 220 (instead of 230) Volt setting on their
Acom 1000, while we have 230-235 Volt Mains in our country. They are not
quite satisfied with 1,070 Watt, but want 1,095 Watt output on 50 MHz.
On 50 MHz; ROFL!!! I am very very happy not to live nearby those people...

3355. Power ON Continuous

Yahoo group: acom-list (1999 — 2009)
Date: 2009-09-28 02:20:46 UTC
From: barbiekenw
Topic: 3355 Message: 3355

One more question and I will stop using bandwidth for awhile.

Is the life of anything shortened by leaving the power switch on all the time, and only using the RCU. The manual says no planned use for 30 min or more, power off is a good idea.

3356. Re: [acom-list] Power ON Continuous

Topic: 3355 Message: 3356

Waist of power consumption would IMHO be the main reason for Acom's advise.

3357. RE: [acom-list] Power ON Continuous

Yahoo group: acom-list (1999 — 2009)
Date: 2009-09-28 10:45:39 UTC
From: N2TK
Topic: 3355 Message: 3357

The last time I turned off the Power switch was when I changed tubes several months ago. My thinking is that the current draw should be fairly low when the RCU is Off. And the amp is a pain to get to since it is mounted near the ceiling of my basement right below my feet in the shack.

When Acom is talking about power off, are they referring to the main power switch or just turning it off from the RCU?

ACOM told me long ago that the timer on the tubes
is activated from the main on/off switch, even though
the RCU is off.....so you must show many, many hours
on your tubes.

I don't believe that is correct. I have about 2K hours on these "new" tubes. They were changed earlier this year. The Power switch on the amp has not been OFF since then. So, the counter is counting only when the amp is ON, at least that is the way mine is working.

From: Hans Remeeus
Topic: 3355 Message: 3360

Indeed it is not correct.

Current measurements with my Acom 2000A:

Mains Supply = 227 Volt

Acom 2000A powered On, but RCU Power Off = 0,11 A
RCU Power On = 0,56 A

After warming up, RCU on STB = 0,81 A
RCU on OPR = 0,84 A

With 108 W RF output on 3.6 MHz = 4 A
With 400 W RF output = 5,1 A

BTW; Filament Voltage = 12,9 Volt

I have "waisted" a lot of my own energy replacing rocker-type ON-OFF switches in amplifiers and linear power supplies. :-) So, I leave amp on and use ICE line voltage protection with a good low impedance ground. I -will- disconnect the amp if not in use for extended periods of time out of the shack. I believe some electronics fail after being turned "off" since they won't come back on. :-)

Hello Mel,

That's a very good idea too.

When I go to work, to bed or whatever, I switch the whole shack 'off'
with a main Mains powerswitch.

BTW; the whole shack is separated from the safety earth of our house and
uses his own clean earth. Apart from this I use a big and screened 3000
VA 220/220 Volt separation transformer between the Mains and the Acom
2000A. The shack is a kind of "island" inside our house.

Hi Mel just a nitpicking comment ....

I have a 32inch "waist"
Standing in line is a "waste" of time

OK bad spell checker......

I use the ICE 240VAC surge protection on the 2000A. I also have their whole house surge protection unit in the circuit breaker panel box!

I turn off the main switch on the 2000A when I'm done operating for the day.

the rest of my ham station runs on 120VAC and is connected to various AC conditioning stuff..from a Furman power conditioner to a 1500VA ups system. I have a "master on/off" switch for the 120VAC run but
I still individually turn devices on/off one at a time to reduce any power up spikes.

Power up spikes and surges are often dependent upon where you live, quality of the power distribution, the integrity of your home's wiring. A common issue now a days is the loss of the neutral line or a loose neutral. That can cause havoc and even serious damage to your equipment and not just your ham gear!

Everyone should inspect their home's electrical distribution once a year...This means inspecting the circuit breakers box to even using an infrared thermometer to see if you have hidden hot spots at your outlets or inside your walls.

My home has the dreaded aluminum wiring!!!! We have pigtailed and nolaxed all and installed new outlets, switches, and lamp fixtures! I have found over the years hot boxes..and circuit breakers that were running hot and almost failed..all of course have been repaired/replaced!

This past December we had a loose neutral behind the electric meter...
This presented a serious imbalance throughout the house!

The reason for this rant is to encourage the amateur operators to respect AC power and ensure it's safe not just for your station but the entire home. A properly operating AC distribution system will also reduce AC RFI challenges

My previous post regarding the condition of the tube in my ACOM 1000 did not result in many answers. I did ask Stan from the ACOM factory in Bulgaria and I uploaded the document received describing tressholds and Tube regime parameters for the ACOM 1000. Also I uploaded a document describing in very detail how to safely remove the covers.

Have fun. 73's Ger PE1CZG

Hi Ger,

I wrote you an e-mail to your personal e-mail few days ago?

Anyways, thanks for sharing this valuable information with us.

Based on this info, what you think yourself what the condition of your current tube is like?

Vy 73, de Kees

Kees,

Yes, thanks for that. I did not found the time to response.
Anyway here is the answer:

Quote
Hello Ger,

I think that the tube is only slightly exhausted but still good. Just to be sure, please repeat only the test (3) with the minimum possible drive power from the transceiver (i.e. with the RF PWR knob fully c.c.w.) and give me the results again.

Hi Ger,

:-)

This is to measure the anode idling current that flows with 5 watts input (should be around 220ma).

If you need to adjust this value, here is the procedure:

Use a small-size, flat-tip, insulated
screwdriver for next

adjustments. On the MAINS PCB, find the two trimmer potentiometers

RP1 and RP2 (marked "BIAS1" and "BIAS2"). They control the
idling

(zero-signal) plate current of the tubes for low- and high- RF-drive

levels respectively.

Please note that RP2 will affect both idling levels, while RP1 - only

the low level. That is why, the high level is adjusted the first, and

only then is set the low level (according to the procedure described below).

b) Select the "Plate Current" information screen on the LCD. Go to

the OPER mode. Apply very small drive power in CW mode (1...5W).

Following the plate current, adjust R2 (BIAS2) to reach 220mA

(200...240 is OK); CCW rotation will increase the current. Don't

exceed 15 seconds with the PTT on. If you need more, repeat the

adjustment 1-2 minutes later.

c) Do not apply any drive during the adjustment of R1 (BIAS1). Select

SSB mode, with the MIC and OUTPUT regulators on the exciter set to minimum.

While monitoring the plate current, adjust R1 (BIAS1) to set the

plate current to 70mA (60...80 is OK); CW rotation will increase the

current. This adjustment does not affect the previous step.

Vy 73, de Kees.

Callum,
as far as the temperature difference indicates different work to do for the 2 tubes, there will be an decrease of modulation quality (audio). Ask Your QSO-partners about Your modulation. If it is ok, You don't need to replace the tubes.

A kind reader of this list suggesting swapping the tubes over, after checking the air-flow first.

I think this seems to be a good idea since nobody has mentioned audio quality as a factor (actually, the reverse).

Comments?

From: marcelo@alternex.com.br
Topic: 3378 Message: 3382

Hello
I am getting a fault signal at start-up of my A2000, saying the heater voltage is too low (around 9.8 v). If I retry enough times the amp will eventually start.
I checked the mains voltage, and it is a bit low, measuring 211V
Could the low mains voltage be the cause, or is this fault located somewhere else?
Mine is an early model, and in the past I have already replaced the infamous molex connector that used to be the cause of low filament voltage.
Thanks
Marcelo, PY1KN

Hello Marcelo,

What is the setting of your Mains Voltage behind the HV-transformer of
your Acom 2000A?

If it is 220 Volt and your mains is 211 Volt, than this could be the
reason of your very very low filament Voltage. Better use the 200 Volt tap!

Such a low filament Voltage could damage your tubes.

Low Mains could be cause and also on early year model ACOM 2000 amps
there was an issue with a connector used in the filament circuit where
the connector burned out, this connector is on teh Low Voltage board
and ACOM has a replacement connector or better yet, remove the connector
and
just solder the wire leads to the PC Board and ELIMINATE the problem
connector !

3385. Heater Light

Yahoo group: acom-list (1999 — 2009)
Date: 2009-10-06 20:21:59 UTC
From: barbiekenw
Topic: 3385 Message: 3385

My reading of the doccument that discusses faults and A2k protection leads to this conclusion:
1. Set tap so it is as close as possible, but lower than, mains voltage.
2. If mains is always higher, go to DEF and change the parameter to indicate Mains is always higher.
3. When mains gets too high, it then causes the heater light on RCU to start to blink now and again. That will be 12 volts or so over the tap setting. This is minor.
4. When the mains is too low, it causes the heater light to turn on solid and shut down the amplifier. This is a more serious and undesireable situation.

Hello Hans
Thank you for the reply.
I'll open the amplifier this weekend, but I believe it is set for 220V. My doubt is if this difference (211 vs. 220V) can be enough for such big difference in the filament voltage. (9.8 or less vs. 12V)
I contacted ACOM and they suggested me to take a look, since there are two other connectors in the filament heating circuit. My amplifier is 1999 production.

Hello Marcelo,

I would try the 210 Volt tap and then check the filament Voltage again.

You can try the DEF parameter setting on the RCU afterwards and check
the Voltage again.

When the Voltage still is too low, then there probably something is
wrong with the PSU.

Take a good look at the filament circuit of the PSU. Perhaps you'll
notice some abnormity.

The difference is very big indeed. Please be careful, because such a low
Voltage really can harm your tubes.

What is the Serial# of your 2000A?

Likely a tube. Try replacing them one at a time. This is the common fault for the common intermittent grid short that develops in these tubes over time..it could, of course, something else. I forget what error code the "bad C2" problem causes.???

Hi Hal,
TNX for your suggestion: I just finished the test. I pulled the tube from a perfectly running ACOM 1000 and I replaced alternatively the two tubes on my 2000A. The result was that there isn't a tube fault!
I also tested both 2000A's tubes on the 1000 and they gave the full output without any trouble.
Any help more ??

Hi Joe,

The next best guess is a bad C2 on the lower power supply board stack. These capacitors are known to fail. I have pasted below one of the emails from the archives.

My dear friends,

I bring tidings of great joy! K3PP's Acom 2000A is back on the air! The BIAS TOO LOW message was the result of a failed electrolytic capacitor (the infamous C2) on the low voltage power supply board. Thanks a 1.0E+06 to Stan at Acom and a whole bunch of you for the help!

The capacitor is a 47uF 250v part. I purchased a fistful from Mouser (part number 75-517D476M250EK6AE3). They were cheap at US$1.72 a piece. I have several here, so if you have the BIAS TOO LOW error caused by C2, let me know and I'll send you one at no charge (while supplies last! HI). Please do not request one as your own spare just in case you "might" have the failure. Please confirm the blown capacitor before requesting one.

The low voltage board is the bottom board in the stack next to the big transformer. It's a bit of a pain to get to it, but feasible with a little patience and care. If you have the C2 failure, it should be noticeable with the naked eye right away. My capacitor had a big bubble protruding from between the leads. There was no doubt it was fried. If you replace yours, remember it's an electrolytic. Polarity matters! Many of us learned this from experience ("experience" is just a euphemism for having made enough mistakes to hopefully learn from them!).

Here are links to photos (courtesy of Stan at Acom). I will try to take a photo of the blown capacitor too. We should probably put them on the Acom list web site with the other photos.

The stack of power supply boards:
http://k3pp.com/Station/Acom2000A/HV
<http://k3pp.com/Station/Acom2000A/HV&LV_Stack.jpg> &LV_Stack.jpg

The low voltage board showing the location of C2:
http://k3pp.com/Station/Acom2000A/LV_Bias1.jpg

I also purchased a pair of NOS GU74b tubes from Vine Antennas. It turns out that wasn't the problem, but at least I now have the spare set ready to go if I need them. Ron GW3YDX of Vine is a GREAT guy!
----------snip----------

VY 73 ... and to all a good night!
de Glenn K3PP

Hi Hal,
TNX for your suggestion: I just finished the test. I pulled the tube
from a perfectly running ACOM 1000 and I replaced alternatively the two
tubes on my 2000A. The result was that there isn't a tube fault!
I also tested both 2000A's tubes on the 1000 and they gave the full
output without any trouble.
Any help more ??

If anyone finds out what causes this, please let us all know. Every once in a while I will get the same symptom with my 2000a. It never happens when the 2000a is running. Hit POWER ON and then it starts fine. Tried changing the tubes. No difference.

It is a very infrequent problem for me.

HI,
Yesterday while working the K4M guys running about 1 KW the rig bounced out to standby. When I went back to operate then the famous G2-Low Voltage 000v displayed and the rig turned itself off. I let it set for 30 minutes and tried again. I got exactly Joe's response when the 2000A turned itself off again after warm up. I replaced the 2 tubes with the spare set I got...same result. I plan on replacing the original tubes in it and then asking the ACOM folks for guidance. I'll try and see if I can get down to the low voltage board and see if C2 looks funny or tests weird in the meantime
I'm fairly disappointed as this amp was bought new less than 2 months ago and I've done everything as suggested by ACOM. I was really excited to try it out and see how much I could stress it during the upcoming CQWW-SSB contest.
Outside of a bad varistor you can get at from the bottom ,the C2 and a bad tube or two is there any other known reasons for the Low G2 voltage that anybody is aware of?
73 and I remain,

Hi Lew,
I'm sorry to read about your joining my same problem.

Today I tested the "famous" C2 (it was good) and I put a new one anyway.
I also tested and changed the varistor (it was good) on the screen grid,
as read on http://groups.yahoo.com/group/acom-list/message/496.
The problem remainS the same: G2 too low voltage 012V (sometimes 010V).

Too bad :-(

Hello OM,

This means that the Filament Voltage level of the linear is too low and
your linear protects himself by shutting off.

Which type of Acom linear are you using?
What is the value of the Mains Voltage in your town?
What is the Mains Voltage setting of the transformuer of your linear?
What is the reading of the 'FIL-V' on the display of your linear?

Pull the plate off the bottom where the tube bases are. The 4-pin connector is probably burnt. I had this last night just as CQWW was starting. Talk about lousy timing!

I cut off the connector and soldered the wires direct. Fixed! It's a VERY cumbersome location, so it won't be too easy.

I figured it out by searching the email archives! You guys are awesome!!

From: Dennis Vernacchia
Topic: 3395 Message: 3398

If you MAINS voltage is not low.....there is a second connector that also burns out on the low voltage board at bottom of stack of
PC Boards in front of the High Voltage Transformer (Corner of board) and I believe
it comes fight from the transformer filament winding.
(The first filament connector is in the plenum under the final tubes)

The connectors are VERY difficult to unsolder

The best thing to do since the circuit boards that have these 2 connectors where not designed very
well to allow easy de-soldering of these connectors (Holes in PC Board are too small and the solder
pads and plate thru can be easily damaged) is to carefully cut awy teh plastic of the
connectors and then de-solder 1 pin at a time and remove from the circuit boards.

The filament connector that is located under the plate of the final amplifier tube plenum
is VERY DIFFICULT to get at and one lead of a resistor that goes from the VERY SMALL
circuit board should be unsoldered from the tube socket end.

If you are not VERY Proficient at soldering or have the correct soldering iron with controlled heat and
correct tips and DE-soldering tools, I recommend you let a qualified technician do the repair.

What you are doing is removing both connectors from the circuit boards and soldering the filament
wires directly into the circuit board holes of the board. Be careful not to mix up wires so mark them as you
remove the wires from the connectors.

The holes on the small circuit board in the tube plenum have plated thru holesa nd one has
to be very careful to not pull out the plate thrus when removoing each of the 4 pins from the board.
(If you do, by accident, pull out the plate thrus, then when you solder the wires directly
to the PC Board, be sure you solder the wire to both he bottom AND THE TOP of the board.)

Replacing both connectors is a 1 1/2 to 2 hour job for a well qualified tech and a 4 to 6 hour
nightmare for those that have never dealt with very difficult de-soldering

of pc boards
that has hole and pad sizes too small for the connectors pins.

Find a tech that also has good eyesight for close in work - this is NOT a
fun job for us old timers !

From: rolandguidry70578
Topic: 3399 Message: 3399

What luck during CQWW! Amp 2000a has shutdown. I unplugged unit from 240v outlet and it came back to normal, then after a few minutes it shutdown again. I have checked mains voltage at wall outlet and it is 240 AC. This amp. has performed well since 2006, with no problems. Nothing has changed in my setup. So how do I fix this, anyone have any ideas? Thanks in advance.

From: Dennis Vernacchia
Topic: 3399 Message: 3400

What is the error message you get just before the amp shuts down ?

One of the current shut down triggers is either LOW MAINS voltage or, worse yet,
if not a MAINS problem, ...the connectors (there are 3 of them) in the filament circuit that burn out.
(2 are on the low voltage board at bottom of stack of PC Boards in the power supply and control area
of the amp and the 3rd connector is inside the air Plenum for the final tubes.
(You must remove the screws along the outside edge of the plate on bottom of amp
under the finals)

This is a common problem with early vintage ACOM 2000 amp made before and I think just after year 2000

What is your serial number, I believe if I recall the first digit is the year
ie 9 is 1999 and 0 is 2000 etc

The solution to the filament connector burning is to remove the connectors and solder the wires
directly to the PC Board

They are not easy to get at and required a fair amount of mechanical dis-assembly and good soldering technique
and the right soldering and de-soldering tools to remove the burned connectors.

If you are not a great tech for soldering or have poor close in
eyesight ....do not even attempt this or you will damage the circuit boards as the connectors
need to be cut off the boards and the connector pins de-soldered 1 at a time

or you will inadvertently wind up pulling the Plate Thrus out of the solder pads and or lift the pads right off the circuit board.

If you pull the Plate Thrus of the pads out of the circuit boards, you will then have to solder the wires not only to the bottom but
also the top pads/traces of the circuit boards

3402. Automatic changing of ACOM 2000 Antenna Selection

Yahoo group: acom-list (1999 — 2009)
Date: 2009-10-28 13:07:55 UTC
From: James Thresher
Topic: 3402 Message: 3402

I wonder if anyone can suggest a method for getting the ACOM 2000 to select a specific Antenna setting through external control. We have a number of antennas (multi-band) that can be switched between one of two stations, both using ACOM 2000's, rather than having to remember to change the antenna settings on the ACOM (A1,A2 etc) manually, i would like to automate the switching. As the antenna's are multi band we cannot just pre-set the correct antenna for each band, we are also not able to use the ACOM antenna switch that the 2000 can control.

Thanks

James
I think you need to add the Acom remote antenna switch for the 2000a to do what you want . The ACOM 2000S is a digital control unit designed to provide fully automatic antenna switching capabilities. When used in combination with the ACOM 2000SW and the ACOM 2000A Automatic HF Linear Amplifier, antenna selection information generated by the ACOM 2000A is communicated to the 2000S. The 2000S displays the currently selected antenna and drives the control signals needed to operate the remotely-located ACOM 2000SW.
In addition to the ACOM 2000A control port, the 2000S includes a general-purpose RS232 control port. This port can be driven by a pc, allowing the 2000S/2000SW combination to be used in environments where computer-controlled switching of multiple antennas is required.Software is available for automatic tuning of all antennas on all band segments when using the 2000S and 2000SW with the 2000A. This DOS software is written to support the Yaesu FT-1000MP as the computer-controlled signal source. It also requires a special set of cables. Contact ACOM for more details.

Subject: [acom-list] Automatic changing of ACOM 2000 Antenna Selection

I wonder if anyone can suggest a method for getting the ACOM 2000 to select a specific Antenna setting through external control. We have a number of antennas (multi-band) that can be switched between one of two stations, both using ACOM 2000's, rather than having to remember to change the antenna settings on the ACOM (A1,A2 etc) manually, i would like to automate the switching. As the antenna's are multi band we cannot just pre-set the correct antenna for each band, we are also not able to use the ACOM antenna switch that the 2000 can control.

Thanks

3404. Using the 2000 in a vertical position

Yahoo group: acom-list (1999 — 2009)
Date: 2009-10-30 03:21:29 UTC
From: arnie lewin
Topic: 3395 Message: 3404

To all:

Is anyone using the 2000 on its side, in a vertical fashion, and have you experienced any problems?

Certainly due to the weight, the power transformer is closest to the floor.

Thank you

arnie

Hello Arnie,

I would not suggest this.

Very important is an *unobstructed exhaust area* of the amplifer. You
should keep a minimum distance of 50 cm (20 inches) to the exhaust.

The air flow of the tubes always is in a vertical direction. So is every
air flow of heath and warmth.

When you use your 2000A on its side *a completely free air flow of the
tubes is not possible*.

On your own risk you could try it, but take extra notice on the
temperature of both the tubes. I would be extremely careful on this item!

Hi Group,

I have a Acom 1000 amplifier that is not even a week old, purchased new from Array Solutions on 10/23/09, delivered 10/27/09. The amp is in 'Mint Condition' and has maybe an hour total operating time. Comes with all original packing/manuals, plus the 2 year factory warranty. After operating this fine amp, I decided to go the auto tune route, although this amp is very easy to tune and works great. Please email me with questions (n0yk@wbsnet.org) or I can call you and we can talk.
Asking $3050 shipped CONUS via FedEx.

Thanks,
Chad

Hello,
enquired with ACOM before purchase and got an OK.
Have been running a 2000 in this position since many years, without
any problems.

If proper airflow can be maintained, specs seem to indicate that the tube
can handle operation in any position.

Topic: 3410 Message: 3411

I've only checked it against two different Bird 83s into a precise 50 ohm dummy load, and only at 1500W. The 83s are rated at +/- 5%. Both gave the same reading. With the last green light lit and just on the verge of lighting the first red light, I get 1400W out of each of my 2000As. I have to have the first red light lit and nearly turning on the second red light to get 1500W.

No other data. I usually run with the first red light flickering.

I'm sorry Barry - my fault - I need to read the questions :-)

Not sure about VSWR accuracy. It seems to agree with my transceivers pretty well..but that's a VERY subject reply.

I'm not home or I would check it. You can use an antenna tuner and 50 ohm dummy load and adjust the tuner to present a 100 ohm load and then a 25 ohm load and see if you get 2:1 in each case. That's what I would try if I was near the home QTH - which I won't be for weeks.

This is a guess, Barry. I would think that if the power reading is accurate (as Hal confirms), and if the algorithm used by ACOM to calculate VSWR uses Forward and Reflected power, then the WSWR is accurate. Good data in implies good data out, but this is algorithm dependent.

For what it is worth, the VSWR on my ACOM 1000 agrees well with my PALSTAR Watt/SWR meter, although I have no idea how well the PALSTAR is calibrated.

All of this is circumstantial evidence that suggests ACOM's VSWR reading is accurate, but I guess the only way to know for sure is if some of the list members have compared it to accurately calibrated WSWR meters (which is what you were looking for, I suspect!)

Appreciate the responses and it makes sense that the Acom would be fairly accurate. The reason I asked is that my Orion indicates a significantly lower SWR (Acom bypassed) and my K3 an even lower SWR. I'll trust the Acom and might need to do a little antenna work . . .

Please share your results Barry! The very best way I know to do it with the items we tend to have around the shack is to:
1. Get known accurate resistors around 100 ohms and 25 ohms. Put them on an antenna analyzer and check its accuracy. Most of the MFJs and the 4170s are quite good. Make up a little calibration correction table for the antenna analyzer if it needs it.
2. Put a 50 ohm dummy load on the antenna side of an antenna tuner, and using your calibrated antenna analyzer, adjust the tuner so the rig(s) see 100 ohms R and j=0. Then check your gear. It should be 2:1. Then try 25 ohms. It should be 2:1 again.
3. Check some intermediate points and for ACOMS, which are rated up to 3:1, I would check the high and low impedance points at 3:1.
4. I'd check VSWR vs. power as well. When you get down to small signals on the rectifier diodes that make up the SWR bridges, the diode drops start introducing a lot of error. This may be why the ACOM in straight-thru looks different than the transceiver. I suspect the ACOM at 1KW and 2:1 may read quite different at 50 watts going through it. I'm guessing that's where the discrepancies you see may be coming from. I have to check the ACOM schematic and see what diodes they used. In the Alpha amp bridges they use shottky-barrier diodes which have very low drop and provide good accuracy over a wide range of power..they also get easily blown out by nearby lightning strikes as they are transformer coupled right onto the antenna jack. Some of the manufacturers use plain old silicon diodes which won't blow, but are less accurate for metering. Don't know what's in the 2000A. The inaccuracy increases as the power levels decrease.

The lower SWR at the transceiver with the amplifier by-passed could be due to extra reactance of the bypass circuit. Remember, the amplifier samples the power/SWR right before its antenna output. There is circuitry (which includes the vacuum relay and some other components) between the coupler and the input connector of the amplifier.
This circuitry is not exactly 50 ohms connector-to-connector - it is designed to be as close as possible to 50 ohm but there is a small amount of reactance associated with it. Now, if this reactance is with the opposite sign of your antenna reactance, the "parasitic" reactance acts in your favour and decreases the overall SWR. In other words...you have a tuning compoenent which cancles out the SWR to some level. So if you have two swr meters - before and after the amplifier you'll see the effects of this - small but present.
I never measured my ACOM 1000, but in the heathkit SB-200 it is very noticeable - the amplifier uses an open-frame bypass relay and a very long directional coupler which is probably far from 50 ohms due to its mechanical construction.

Funny you should ask. I just finished building my LP-100A. I don't know how accurate it is because I haven't got the gear to calibrate it properly, but it seems to read lower than the 2000A LEDs. This is not scientific at all, and could very well be wrong! If I do some better tests, I will let you know.

Ignoring very long/lossy lines, SWR is constant along the line
although impedance varies - it doesn't matter where on the line you
measure SWR.

OT, but a Smith Chart demonstrates this elegantly (see
http://www.arrl.org/tis/info/pdf/q1106037.pdf) - the load represented
by an antenna creates a circle (of constant SWR) on a Smith Chart with
impedance varying along the circle as you move away from the load
(half wavelength per circumference) but SWR staying constant
(represented by the circle's radius).

An excellent point, although as Barry points out, technically it is the impedance, not the SWR that varies. I added ~60 feet of RG-11 to the shack end of my 80M dipole's RG-213 feed line (actually it's a too-low-to-the-ground curtain dipole) to make the impedance the amp "sees" closer to 50 ohms. Obviously this had no effect on the impedance at the dipole feed point, but it made me feel better seeing a SWR of 1.1 in the shack as opposed to 1.7. I'm sure the efficiency of the antenna system was not any better, but the reflected power coming back into the shack is lower.

Paul,

In your case, you used the 75-ohm section of RG-11 in conjunction with the RG-213 to actually change line VSWR at the shack end of the cable. I would have placed the RG-11 at the antenna end and kept the RG-213 at the shack end. In that case, the 50-ohm RG-213 VSWR actually does change with the addition of a varied RG-11 line length. While the VSWR on the RG-11 section (between the antenna and RG-213) remains fixed with changing length, the VSWR on the RG-213 does in fact change -- something that can not be accomplished by changing the line length with only a run of RG-213. With RG-213 only, no matter how much you change the line length the VSWR does not change (absent change from line loss). It sounds like you accomplished the same result but with a reversal of RG-11 and RG-213.

It takes a transformation of three terminal Z values to do that starting with Z1, the antenna feed-point Z, Z2 the matching section's characteristic Z (75-ohms in this case), and finally, Z3, the output target Z (50-ohms in this case).

Although you may think that efficiency was not improved, it actually would improve in the case where a fixed 50-ohm solid state PA is used without an antenna tuner. With a vacuum tube output with its Pi-L output network (e.g., ACOM 2000) or a fixed-Z solid-state amplifier + an antenna tuner, then the added increase in overall efficiency is probably quite minimal.

Paul, W9AC

>Paul, W9AC

Agreed Paul. What you are saying is sort of analogous to using
the 1/4 wavelength of 75-ohm "transformer" method to feed delta
loops. I'd rather have put it at the feed point end, but that was
55-feet in the air strung between two towers (and in the winter.)

I had several spare random lengths of RG-11 laying around and I simply tried them one at a time in line and just outboard of the ACOM-1000 until I got a piece that gave me a SWR of 1.1. I didn't do any calculations as I just wanted to lower the 1.7 to below 1.5. I guess I happened to have a piece close to the ideal length as I ended up with 1.1:1.

The amp is indeed happy with up to 3:1, but I need to have 1.5:1 or less on all my antennas or I can't sleep. I know the math means I'm chasing the law of diminishing returns worrying about SWR at these levels, but that's me!

73, Paul VE1DX

3426. acom 1000 on 120v

Yahoo group: acom-list (1999 — 2009)
Date: 2009-11-08 13:16:58 UTC
From: AB2E Darrell
Topic: 3426 Message: 3426

Hello all,
I have a question for you 1000 users. I am going to need an amp that operates on 120v (this will be on a dxpedition in the Philippines, and in the area I will be visiting, 220v is extremely rare).
Can all 1000s switch from 220, or does it have to be ordered that way>? In the specs page it seems to indicate it would need to be ordered for 120.

Secondly, for anyone using the 1000 on 120v, can you tell me what the line current draw is?

Thanks and 73,
Darrell AB2E

Hi Darrell,

When I ordered mine, I was asked if it would be ran on 240vac, otherwise the change would of been done at the dealer for 120vac. Under the cover of the amp there are several taps for selecting the proper input voltage to the transformer, so I'm guessing a call to the dealer, changing a few taps and you'd be set. Doesn't look hard at all, just change the plugs around, this is only my best guess as I don't really see any information on this in the manual.

On your line current draw questions, the manual shows 2200va, so you will need a dedicated 120 vac @ 20 amp circuit for this setting. On peaks, I bet you draw anywhere from 17 to 19 amps @ 1000 watts + output of the amp.

Hope this helps.

73,
Chad

You need to change the taps on both the low and high voltage transformers. Not a difficult task. Use the table on the schematic, which you can find in the Files section, under this name:

Hi Jim,

I have the 2000A. Typical warm up operating temperature is around 104-110F or about 40C.

I only do SSB but can get wordy! I have seen the temperatures slowly climb up to 10 squares on the RCU ...100C or about 212F.

The worst case for me has been 12 sq or 120C or about 248F. The amp works just fine and cools down quickly.

You do have a wide temperature operating range..I believe at 150C or 300F you get an over temperature fault and the amp faults to a long cool down. I think you can find the tube's temperature parameters on a tube spec sheet. The manual does not indicate much details. I have a 2001 vintage operating manual.

I also cool the amp [leave it on] prior to shutting down I always shut down when the temperature is 40C or about 104F.

I have a Taylor outboard digital thermometer to measure the exhaust air directly out of the rear chimney. This also gives the temperature in "F" as the 2000A only displays "C".

There is a variance between the internal and external temperature readings but that's expected and not a problem.

Oh, finally the 100+ degree exhaust air really helps keep the radio room warm and toasty on these cold Arizona 80 degree [F] days!!!!

Maybe I missed it in manual, but was wondering what temperature triggers the external fan to turn on? I know I could run a test for this but rather not. :-)
Thanks

Marty & all thanks. A ham I talk to on 75 meters is having some trouble with his 2000A and he was worried about going into the 60C range and I told him that's ok and that it could operate quite higher than in the 60C range. He asked me the magic question, "How high", and I couldn't answer that for him. I have had mine go near 70C but I guess I am not too long winded but I knew they can operate at a much higher temperature..

I will pass along all the fine info I have received from the group to the Ham having problems with his 2000a.

Who is he and what problems is he having with his 2000A?

Sounds more like he's not familiar with it instead of having problems.

Gosh, I found the information reading my amplifier documentation and viewing older posts.....Sarcastically, I will save the lazy ones from researching the wealth of information in older posts on this reflector!

From the tube specification sheet.....maximum operating envelope temperature 200C or about 392F

From Acom....Exhaust air temperature when the optional 24VDC fan is mounted is accelerated at 90C,194F, and slows down when the exhaust air temperature drops to 80C,176F.

Full measurement scale on the RCU is 130C,266F, 10C,18F degrees per bar. and is an acceptable working range.
A ">" sign appears when the scale is overflowed and protection trips in at 150C,302F threshold.

If the temperature is higher than 90C,194F, when you shut the amplifier off, the tubes are instantly powered off but the blower continues to continue cooling until the temperature drops to 80C,176F

Another protection system monitors the air motion in the tube deck volume. This would prevent the control system from being let down while measuring a low temperature but still standing air above the tubes. You'll get a "low airflow" message in such conditions. [better English]...If you lose air flow or the air flow is reduced you'll get a low airflow message]

Typically this can be caused by a dirty air filter etc.

Again when the amp reaches 150C, 302F the amp faults and protection kicks in. The specs on the tube states maximum plate temperature is
200C, 392F...so you can see Acom has designed plenty of room to ensure you never cook your tube!

I also strongly recommend you allow the tubes to cool down to
40C,104F or no more than 50C,122F This will slowly cool the tube and reduce thermal shock.

Hope this helps....

Martin KA7GKN

Just using an ACOM-1000 here, but I couldn't agree more. I
NEVER shut it off until the exhaust temperature drops below 40 C, and
after the 150 second warm-up, I usually leave it for an extra minute
or two before transmitting. It might be overkill, but I haven't
missed anything rare because of the extra time on warm-up. On
cool-off, even if you have it driven up to 70-80 C, it will drop to
40 C quite quickly. An ounce of prevention! Still on the original
tube after 3 years of 5-8 ours of daily use. :-)

Guys agree with all said.

Have read manual & seen all mentioned but it dosn't come out & mention a safe operating temp....but then I can assume 149c....then I don't want to keep running mine in the 140 range although I don' think it' made the 70c range. Already mentioned foam filter cleaning to him.

Just trying to get a question answered for the guy. This is what I get for trying to be helpful to a fellow ham.

149 c is safe, period. Eod.

Thanks Martin for the reserach and answer to my question about opeartion of external fan. I'll tuck this info inside my Acom folder.

Mel, K0PFX

Subject: [acom-list] Re: Normal Safe tube operating range

Gosh, I found the information reading my amplifier documentation and viewing older posts.....Sarcastically, I will save the lazy ones from researching the wealth of information in older posts on this reflector!

From the tube specification sheet.....maximum operating envelope temperature 200C or about 392F

From Acom....Exhaust air temperature when the optional 24VDC fan is mounted is accelerated at 90C,194F, and slows down when the exhaust air temperature drops to 80C,176F.

Full measurement scale on the RCU is 130C,266F, 10C,18F degrees per bar. and is an acceptable working range.
A ">" sign appears when the scale is overflowed and protection trips in at 150C,302F threshold.

If the temperature is higher than 90C,194F, when you shut the amplifier off, the tubes are instantly powered off but the blower continues to continue cooling until the temperature drops to 80C,176F

Another protection system monitors the air motion in the tube deck volume. This would prevent the control system from being let down while measuring a low temperature but still standing air above the tubes. You'll get a "low airflow" message in such conditions. [better English]...If you lose air flow or the air flow is reduced you'll get a low airflow message]

Typically this can be caused by a dirty air filter etc.

Again when the amp reaches 150C, 302F the amp faults and protection kicks in. The specs on the tube states maximum plate temperature is
200C, 392F...so you can see Acom has designed plenty of room to ensure you never cook your tube!

I also strongly recommend you allow the tubes to cool down to
40C,104F or no more than 50C,122F This will slowly cool the tube and reduce thermal shock.

Hope this helps....

Others here have described how the nuts drop off inside the unit when unscrewing the filter screws.

Anybody come up with a way to removing/cleaning the filter that doesn't involve such nonsense?

Nope. I just vacuum it from the outside and that seems to get
95% of the crud out.

Just a heads up on the screws. the threads are a cinch type and if you over torque your screws they may and often twist off!

I suggest you use a #1 pozidrive bit as the #1 Phillips head does not fit well...these are metric heads and threads!!!!! #2 Phillips head is too large.

When tightening them do not use any power driver as they have way too much torque ..even at low clutch settings.

Screw by hand slowly until it stops. No pressure...if you must torque any further less than 1/8 turn is more than enough.

When unscrewing carefully press down lightly to ensure the bit seats well into the screw head. Then with a light touch twist counter clock wise...[for those of you using a digital watch you'll have to figure out what that means] Again it's preferred that you do this by hand and not use a power driver as tempting as it may be.

There are plenty of screws within the cover to ensure minimal RF leakage so don't worry about not torquing the daylights out of them.
You simply want to ensure the cover is evenly secured and all the screws are [key word here] "SNUG"

I have the 2000A so the filter snaps on from the outside and I wash it once every 2 months. I also have a metal mesh pre-filter as in AZ it's really dusty here!

Kees,
Thanks tip.
Have done this. Not sure whether it was effective or not. Guess I'll have to put in some more hours in WAE-RTTY and watch the air temp.

Too bad the filter isn't notched around the screw holes. Once notched one might slightly loosen the attach screws and flex the filter out. Of course, one has to first remove the filter to notch it.

Hi Brian,

Yes it works fine that method. Keep the hover hose close to the toothbrush when you clean the filter. No more need to remove the filter at all :-)

See yah on the bands,

3449. Acom 2000 bias too low again !

Yahoo group: acom-list (1999 — 2009)
Date: 2009-11-15 22:25:34 UTC
From: la7sl
Topic: 3449 Message: 3449

Hi !
Our old Acom 2000A is having problems. I get the famous bias too low (-75V) message just as "countdown" is finished. It does not show any error message during countdown (warmup). I have measured the bias output from the inteface board, and it shows -124 volts during countdown and immediately goes to -75v at countdown finish. For those who know this circuit there are two possibilities : The circuit gets a false ENABLE from CPU and thinks it is in OPR with PTT closed, OR there is a false load coming on the BIAS line at the very moment countdown is through. I have excluded the false enable option by checking this input with a scope. I have also tied the INHIBIT input to high to block any ENABLE pulse not visible on the scope. It still changes BIAS. I have also measured voltage drop through the resistor (R50)in series with Q9 (the dropping transistor) to see if it passes any current. No current is passed here at any time. So the first possibility is excluded. It must then be the second. WHAT can suddenly load the bias line at the very moment countdown is through ? You can exclude the bias measurement circuit on the tube deck, as nothing changes here in that very moment. The two bypass caps and the choke can be excluded, nothing changes there either. The only answer left is the tube(s). Now: what changes here in that very moment ? Answer : G2 comes on at + 10V (STBY level),-and plate voltage comes on. I have seen many explanations here about a grid>cathode leak ... This will most certainly NOT develop at this very moment as the heater is already up and running full temp.
The only possible answer seems to be a G1>G2 internal leak in the tube. Any comments gentlemen ? My brain is getting old and slow :-(

The line in my mail to group:
"...I have also
measured voltage drop through the resistor (R50)in series with Q9 (the dropping transistor) to see if it passes any current. No current is passed here at any time. ...."
SHOULD read : "No current change is measured here at any time"
In other words ; I can not see any change inn passed current when BIAS drops after countdown. R50 passes a very small current during warmup, but I see no sudden change.
Peter

From: Hal Kennedy
Topic: 3451 Message: 3452

To my knowledge, no Barry, there is no way to go into the software from the RDU and change anything. I once asked ACOM if I could change the temp setting for the external fan to come on. Its 90C and I'd prefer something like 75C. Answer was: not possible to change anything from the RDU.

I have studied the schematic RE: the arc-fault detector. It is easy to lift a wire and shut it off that way. It is also easy to change one or two component values and make it less sensitive. I never did - I finally decided it was doing what I wanted it to..

From: pa7two
Topic: 3454 Message: 3454

Hi all,

I was not aware of the fact that Acom currently produces an Acom 1011 amplifier with 4Cx250B tubes these days?

I am surprised about the tune change. A 4CX250B has only 250 watt dissipation capacity, a draw back to me compared to the GU74B tube which has 800 watt dissipation capacity...

According to the manual,these 4CX250B tubes should not replaced by the user, too complicated process, and unit has to go back to the dealer in that case...

Vy 73, de Kees.

Difona showed the Acom 1011 in Dortmund on December 5th.

Read this about the tubes:
http://www.w8ji.com/vacuum_tubes_and_vaccum_tube_failures.htm
The actual plate dissipation is the time-integrated amount of anode
current and voltage. In an amplifier with steady current, anode
dissipation is found quite easily by multiplying the accelerating
voltage (anode-cathode potential) times anode current. In an amplifier
system, dissipation is a complex function of the constantly changing
anode voltage and current. In such systems, a very close approximation
of anode dissipation is given by multiplying average anode current by
average anode voltage, and deducting the useful power extracted by the load.
And more...

500-700 Watt output in most case is enough for easy contacts (without
collecting the Worked All Neighbours certificate) and in several
countries more than allowed.

4CX250B tubes are easy to obtain.

The 1011 is compact and easy to handle.

The mechanical construction is very solid.

Noise reduced fan.

Heat up time of 30 secs.

The price is within reach for many people.

Another excellent product of Acom!

From: Kees - pa7two
Topic: 3454 Message: 3457

Some corrections Hans,

The tube manufacturer stated a minimum heat-up time of 60 seconds. This is also stated in the manual -> :
NOTE: A minimum 30 seconds cathode warmup time is required but 60 seconds is recommended by the tube producer.

The basis of the Acom 1011 model is based on the Acom 1010, nothing changed to better or greater performance in the new model. The Acom 1010 was a trimmed down version of the Acom 1000 and the new Acom 1011 is exactly the same range.

In comparison to in example the Acom 1000, the Acom 1010/1011 has no QSK capability because the relays are normal 2 x8A/250VAC types instead of vacuum relays, has cheap CB1.1 & CB1.2 & CB2 CAPs around the two Plate chokes, and has no 50MHz capability due to lower transformer power-rating, lower HV-diodes current rating, less HV-filter capacitance, reduced RF-Tank coils size, the padding caps power rating is lower and lower cooling air flow.

So, having the above in mind, if I had the choice of a Acom 1011 or a Acom 1010, I would choose the latter. Mainly due to the far more rugged and easy to get GU74B tube and furthermore it is always better to use one instead of two tubes if the aim for the output power is exactly the same. (Both are advertised for 700 watts RF).

countries more than allowed.

4CX250B tubes are easy to obtain.

The 1011 is compact and easy to handle.

The mechanical construction is very solid.

Noise reduced fan.

Heat up time of 30 secs.

The price is within reach for many people.

Another excellent product of Acom!

Kees,

Did you see the 1010 and 1011 next to each other? I did... In Dortmund.

Look at this site and you will see the differences:
http://www.wimo.com/cgi-bin/verteiler.pl?url=amplifier-acom_e.html

---> Heat up time reduced to 30 seconds <---

You cannot compare the 1011 with the 1000, because it is another price
range; 1575 vs 2395 euro.

Of course you prefer the GU74b... ROFL!

Hi Hans,

Please read my previous message carefully, I stated "in COMPARISON to the Acom 1000" and did a technical sum-up why this is a cheaper, less robust amplifier and has furthermore less functionalities.

In the manual is a 60 seconds heat-up time mentioned because the tube manufacturer asks for this fact. I copied the text from the Acom 1011 manual. So, the 30 seconds heat-up time is incorrect and it shall shorten the tubes life time.

I do not understand your comment about the tube (LOL) : -> My choice is solely based on the technical fact that the GU74B is able to dissipate 800 watt on the anode and the fact that one single tube is used to obtain the same output power. I think it is very hard to challenge those facts Hans.

If one needs, the Difona website shows photos of both amps and furtermore has both manuals made available on-line with the schematics.

Hi Hans,

Let us get things straight here, I was telling the Acom reflector members that a new Acom 1011 amplifier was brought to market. Next you came up with some incorrect / in my opinion questionable statements, on which I replied.

FYI: I use an Acom 1010 for portable usage myself, based on your recent statements I am almost sure to the full extend you are not. This means that your judgements are based on non operational exposures. The Acom 1010 is a good quality amplifier, I am very happy with the device, but it has (logical) drawbacks compared to the higher scaled / prices Acom models.

So back to the reason I replied to your message. Reply with correct facts and I fully agree on the statements. This applies to anyone. However, it seems like some of us always things they know better. And when in that case I know for 100% that the statements are questionable, I reply with an explanation why I think that is not the case.

Hi all,

I was not aware of the fact that Acom currently produces an Acom 1011 amplifier with 4Cx250B tubes these days?

I am surprised about the tune change. A 4CX250B has only 250 watt dissipation capacity, a draw back to me compared to the GU74B tube which has 800 watt dissipation capacity...

According to the manual,these 4CX250B tubes should not replaced by the user, too complicated process, and unit has to go back to the dealer in that case...

Vy 73, de Kees.

From: n4jdu
Topic: 3468 Message: 3468

Hi Guys I too am a new owner of trhe Acom 1000. I started watching the reflector about 6 months ago and remember a discussion about cleaning and keeping lint away from the inside of the Chasis. Well I found a website called www.radiodustcovers.co. that produces custom dust covers in felt+vinyl or in wool/felt. te
hey look quite nice. So if anyone wants a custome cover with call and logo heres the spot. I really enjoy the quiet nature of this amp.
has anyone seen the tuning video and can direct me to it. the TRI system video?

Thanks

Jeff, N4JDU

From: la7sl
Topic: 3450 Message: 3471

Hi all !
The problem was actually an internal leak between G1 and G2 in one of the tubes. This in turn pulled on the G1 bias causing it to go far too low. The tube fault altso caused transistors Q1 and Q2 on the HVSG board (G2 regulator) to fail into short circuit.(Q1 is replaced with a higher voltage type in later production) This brought the G2 bias from 12v to 430V in STBY ! As the amp measuring sequence at startup is G1-g2 etc the RCU showed the G1 bias pull and then the amp went power off. Stan at Acom Bulgaria has been extremely helpful and has given me a lot of good support. This is great service ! Thank you Stan !
Merry Christmas to everybody !

>
> Hi !
> Our old Acom 2000A is having problems. I get the famous bias too
> low (-75V) message just as "countdown" is finished. It does not show any error message during countdown (warmup). I have measured the bias output from the inteface board, and it shows -124 volts during countdown and immediately goes to -75v at countdown finish. For those who know this circuit there are two possibilities : The circuit gets a false ENABLE from CPU and thinks it is in OPR with PTT closed, OR there is a false load coming on the BIAS line at the very moment countdown is through. I have excluded the false enable option by checking this input with a scope. I have also tied the INHIBIT input to high to block any ENABLE pulse not visible on the scope. It still changes BIAS. I have also measured voltage drop through the resistor (R50)in series with Q9 (the dropping transistor) to see if it passes any current. No current is passed here at any time. So the first possibility

is excluded. It must then be the second. WHAT can suddenly load the bias line at the ver y moment countdown is through ? You can exclude the bias measurement circuit on the tube deck, as nothing changes here in that very moment. The two bypass caps and the choke can be excluded, nothing changes there either. The only answer left is the tube(s). Now: what changes here in that very moment ? Answer : G2 comes on at + 10V (STBY level),-and plate voltage comes on. I have seen many explanations here about a grid>cathode leak ... This will most certainly NOT develop at this very moment as the heater is already up and running full temp.
> The only possible answer seems to be a G1>G2 internal leak in the tube. Any comments gentlemen ? My brain is getting old and slow :-(

Hallo Peter,

tnx for ur interisting hint, concerning "bis low"-message for the ACOM2000A.
Do you know, at what year the transistor Q1 was replaced with a higher voltage type ? Can the described failing of the transistors occur in newer production lots as consequence of g1-g2-leak ?
Is the main thing, you want to point out, that the g2-voltage increases to 430 Volt, if that error occurs and therefore the error can be easily located by measuring the g2-voltage with a usual volt meter ?
I think, it would be helpful to other ACOM2000A owners, if you put more details about this error to this web site. For instance answering the qestion weather someone can change the tubes without destroying the replacing new tubes without doing any further measuring when the message "bias low" occurs.

I have measured the bias output from the inteface board, and it shows -124 volts during countdown and immediately goes to -75v at countdown finish. For those who know this circuit there are two possibilities : The circuit gets a false ENABLE from CPU and thinks it is in OPR with PTT closed, OR there is a false load coming on the BIAS line at the very moment countdown is through. I have excluded the false enable option by checking this input with a scope. I have also tied the INHIBIT input to high to block any ENABLE pulse not visible on the scope. It still changes BIAS. I have also measured voltage drop through the resistor (R50)in series with Q9 (the dropping transistor) to see if it passes any current. No current is passed here at any time. So the first possibility is excluded. It must then be the second. WHAT can suddenly load the bias line at the ver y moment countdown is through ? You can exclude the bias measurement circuit on the tube deck, as nothing changes here in that very moment. The two bypass caps and the choke can be excluded, nothing changes there either. The only answer left is the tube(s). Now: what changes here in that very moment ? Answer : G2 comes on at + 10V (STBY level),-and plate voltage comes on. I have seen many explanations here about a grid>cathode leak ... This will most certainly NOT develop at this very moment as the heater is already up and running full temp.

Hi Peter,

Good to hear the problems are resolved. Yes, we as amateur radio community are very happy with the e x c e l l e n t after service from Acom!

A bit weird to read that a faulty tube destroys the Q1 & Q2 transistors, that should not take place. Hopefully using the newer replacements, this phenomenon does not occur any more.

Perhaps you can mention the newer type replacement transistors here on the reflector, specify the brand and exact type.
If I had an older unit I would replace these transistors immediately before any damage could occur. Just like with the resistors in the bias circuit in my Acom 1000 unit!

Hi !
There has been some interest in the G1/G2 issue in my Acom 2000A
Right now I am too busy with Christmas preparations :-) but I will be back after Xmas with a better and more detailed explanation.
But a couple of answers now : I think several different transistors have been used for Q1 on HVSG in different production runs. I do not know what year the specs were upgraded. Check what type is used in your PA ! If it is a 500V mosfet it should be replaced by a 800V type.
Suitable types are (according to Stan) STP9NK80Z or STP10NK80Z 800V MOSFET or similar types. This is not very critical. If your Q2 goes open (it will if Q1 goes) almost any small npn general purpose will do the job. I used BC547C (reverse connections !)
Q1 is very easy to change: Remove top cover, locate Q1 boltet to the chassis (front) just above the HVSG-board. Unplug the connector and replace. The chassis is threaded so you do not have to worry about loosing a nut. (at least it was here) Take care to choose a type that matches the connector. No soldering necessary. Q2 is a bit more tricky... Remember this is a high voltage area !!!! Caps DO keep their charge for quite a while ! It is not possible to measure G2 volts to see if you have this fault. The amp measures G1 first on startup,- then G2. If G1 bias is wrong as a result of such a fault the amp will switch off before you have time to measure. In a case where you do not know if the fault is a G1>cathode leak or a G1>G2 leak,- try to unplug JP2 (310VAC) from HVSG board. Replace top cover using at least 3 screws (there are interlocks) and try to restart.
If you still get BIAS TOO LOW there is a chance you have G1>Cathode leak. If it faults with G2 too low or G2 on before countdown finished you probably have a G1> G2 leak. And last : There is no rule saying you will loose Q1/Q2 if you have such a leak. But this leak PLUS a mains voltage spike may cause it to happen. OR several restarts of the AMP AFTER A BIAS TOO LOW ERROR may do it. If your amp faults to power off there is almost certainly something serious going on. And in this case you should be careful with repeated restarts. I do not think Q1 and Q2 will blow in the newer units with 800V transistors for Q1.
This is the best I can do for the moment ! Back to Christmas preps here :-)
MERRY CHRISTMAS !
LA7SL Peter

Sounds like a bearing starting to fail in the blower. When it is up to speed it self centers and stops making noise. See if the shaft is loose.

Subject: [acom-list] ACOM2000A - terrible noise during POWER ON cycl

As a lucky ACOM2000A owner I ran into trouble after more than 3000 hours of use.

After PA switch on there is a terrible and very loud noise during POWER ON cycle caused by internal blower (not the short sound by load/tune position motors). After few seconds up to 2 minutes the noise disappears and blower sounds like he did for years.
The strange noise sounds like defect gear mechanisms between motor axis and blower or blower wing scratches on blower housing or something else. There are no chips or any other failure indications visible.

Anyone else had this experience before ? Any hint what to do ?

Thanks in advance and 73 de Thomas, DL1AMQ
